Transcript: Joint BBN and X-ray Constraints on keV Sterile-Neutrino Dark Matter, 2024–2026

HEP-Genesis-Agent session record
Project: ramp-research-sterile-bbn-xray

2026-11-02

The conversation verbatim, generated mechanically from the session record.

A Conversation transcript

The exchange verbatim (assistant text as shown to the user; tool calls summarized by name — see the tool-call log for arguments and results).

User (2026-10-21 11:01:50)

Survey recent arXiv work (2024-2026) on sterile-neutrino dark matter. Combine BBN constraints (use the sterile-nu tools for Yp/D/H numbers) and X-ray constraints: which (m_s, sin^2 2theta) regions remain viable? Quantify with tool calls where possible.

Assistant (research mode, 2026-10-21 11:01:50)

Plan:

1. (closed) Use the sterile-neutrino server to compute BBN observables (Yp, D/H, Delta N_eff) together with relic-density constraints across the (m_s, sin^2 2theta) plane. Identify which regions BBN and abundance arguments leave open.

2. (closed) Quantify the X-ray decay-line constraints. Compute predicted line energies and fluxes with the server, then compare them with published 2024-2026 limits from NuSTAR, INTEGRAL/SPI, Chandra, eROSITA and XRISM to bound sin^2 2theta as a function of m_s.

3. (closed) Survey the 2024-2026 production-mechanism literature (Shi-Fuller resonant production with lepton asymmetry, reheating production, scalar decays) and test its viability claims against tool-computed BBN numbers, adding the Lyman-alpha and structure-formation bounds.

4. (closed) Synthesize the d-01 BBN and relic-density results, the d-02 X-ray limits and the d-03 structure-formation bounds into a single table of viable (m_s, sin^2 2theta) regions per production mechanism, with an explicit provenance and robustness check.

5. (closed) Re-extract the quantitative literature claims (f-002, f-012, f-013) as verbatim quotes. Build a verified X-ray limit table at m_s = 7.1, 10, 20, 40 and 50 keV. Then

produce the final per-mechanism viability table in the (m_s, sin^2 2theta) plane (DW, Shi-Fuller with lepton asymmetry, flavor-dependent asymmetry, reheating production), with a provenance column for each entry.

6. (closed) Settle the factor-3 DW relic-density normalization against a published calculation and compute m_th along the DW dark-matter line. Also give a short BBN robustness check: the Delta N_eff bound under the brief's data versus the server's data, and the joint (Delta N_eff, xi_e) bound using dYp/dxi_e ~ -0.25.

Tool calls: `list_agent_files`, `list_input_files`, `list_datasets`, `list_files`, `get_dispatch`, `list_sterile_nu_skills`, `search_arxiv_abstracts`, `search_arxiv_abstracts`, `search_arxiv_abstracts`, `search_arxiv`, `search_arxiv`, `web_search`, `search_arxiv_abstracts`, `search_arxiv_abstracts`, `get_arxiv_metadata`, `get_arxiv_metadata`, `search_arxiv_abstracts`, `search_arxiv_abstracts`, `describe_sterile_nu_tools`, `list_sterile_nu_skills`, `get_arxiv_metadata`, `get_arxiv_metadata`, `get_arxiv_metadata`, `predict_sterile_nu_xray_line`, `load_sterile_nu_skill`, `predict_sterile_nu_xra` `predict_sterile_nu_grid`, `get_arxiv_metadata`, `describe_sterile_nu_tools`, `download_arxiv_full_tex` `predict_sterile_nu_grid`, `predict_sterile_nu`, `scan_sterile_nu_parameters`, `check_sterile_nu_sbl_a` `plot_sterile_nu_bbn_impact`, `predict_sterile_nu_grid`, `read_arxiv_chunk`, `plot_sterile_nu_exclusio` `predict_sterile_nu_grid`, `search_arxiv_abstracts`, `search_arxiv_abstracts`, `read_text_file`, `search_arxiv_abstracts`, `search_arxiv_abstracts`, `post_finding`, `post_finding`, `post_finding`, `download_arxiv_full_text`, `cite`, `predict_sterile_nu_grid`, `download_arxiv_full_text`, `search_arxiv`, `search_arxiv_abstracts`, `post_finding`, `post_finding`, `post_finding`, `read_arxiv_chunk`, `read_arxiv_chunk`, `post_question`, `read_arxiv_chunk`, `read_arxiv_chunk`, `cite`, `post_finding`, `post_finding`, `post_finding`, `post_finding`, `post_finding`, `post_finding`, `post_finding`, `post_dead_end`, `post_question`, `read_text_file`, `download_arxiv_full_text`, `download_arxiv_full_text` `download_arxiv_full_text`, `search_arxiv_abstracts`, `read_arxiv_chunk`, `read_arxiv_chunk`, `predict_sterile_nu_grid`, `read_arxiv_chunk`, `read_arxiv_chunk`, `read_arxiv_chunk`, `read_arxiv_chunk`, `read_arxiv_chunk`, `get_paper_figures`, `search_arxiv_abstracts`, `download_arxiv_full_text`, `post_finding`, `post_finding`, `post_finding`, `post_dead_end`, `search_arxiv_abstracts`, `read_arxiv_chunk` `predict_sterile_nu_xray_line`, `predict_sterile_nu_xray_line`, `cite`, `read_arxiv_chunk`, `post_finding`, `post_finding`, `download_arxiv_full_text`, `cite`, `post_finding`, `post_finding`, `post_finding`, `post_finding`, `post_question`

Survey — 39 tools on 3 servers, 6 read-only probes, 9 papers found.

Recent work from 2024-2026 that the tools returned is mostly about production mechanisms rather than new X-ray datasets. The main papers revisit Shi-Fuller resonant production with large lepton asymmetries. Vogel, Garcia Escudero, Froustey and Abazajian (arXiv:2507.18752) find that asymmetries L >~ 0.5 at T > 20 MeV are consistent with BBN and CMB, and that they open a viable region at m_s >~ 10 keV and sin^2(2theta) <~ 1e-14. That region is compatible with NuSTAR and INTEGRAL/SPI X-ray limits and with Lyman-alpha inferences of a thermal-equivalent WDM mass m_th ~ 4.1 keV. Gorbunov, Kalashnikov and Krugan (arXiv:2502.17374) show that flavor-dependent asymmetries, which work best with inverted ordering, can cancel the BBN limits on mixing and give colder spectra, which reopens lighter masses at smaller mixing. Two other papers extend the picture but were seen only as abstract snippets: a 2026 paper on cold sterile-neutrino DM from inflaton decays during reheating (arXiv:2601.03346) and a 2026 paper on lepton asymmetry saturating resonant production (arXiv:2609.31340). The overall picture is that standard non-resonant (Dodelson-Widrow) production is excluded by X-ray limits combined with structure formation. What survives sits at very small mixing, roughly sin^2(2theta) <~ 1e-11 to 1e-14 depending on mass, and needs either resonant production with BBN-compatible lepton asymmetry or a non-oscillation mechanism such as reheating or scalar decays. A web snippet (not citable; no arXiv ID found) says eROSITA eFEDS line searches over 1.8-18 keV, and eROSITA diffuse limits more broadly, are now the strongest in their band.

Warning: I had no sterile-neutrino BBN tool for Yp or D/H, so none of the BBN statements here are numbers I computed. They come only from paper abstracts and still need to be checked by calculation.

Quantities worth checking: Radiative decay rate Gamma = 1.38e-32 s^-1 (sin^2 2theta / 1e-10) (m_s / keV)^5 and the line energy E = m_s/2, to convert X-ray flux limits into sin^2(2theta) limits; Shift in Yp from Delta N_eff and from a nu_e asymmetry xi_e (roughly dYp/dxi_e ~ -0.25), checked against the measured Yp ~ 0.245 +/- 0.003; D/H as a function of Delta N_eff and eta_b, checked against (2.53 +/- 0.03) x 1e-5; Lepton asymmetry L(m_s, sin^2 2theta) needed for Omega_s h^2 = 0.12 under Shi-Fuller production, compared with the BBN-allowed |xi_e| <~ 0.03 at T < 1 MeV and larger L above 20 MeV; Thermal-equivalent WDM mass m_th for each point, compared with Lyman-alpha bounds (m_th >~ 4-6 keV); Dodelson-Widrow abundance Omega_s h^2 ~ 0.1 (sin^2 2theta / 3e-9)(m_s / 3 keV)^1.8, to confirm that pure non-resonant production is excluded.

Plan — 4 lines of investigation:

1. Use the sterile-neutrino server to compute BBN observables (Yp, D/H, Delta N_eff) together with relic-density constraints across the (m_s, sin^2 2theta) plane. Identify which regions BBN and abundance arguments leave open. — This answers the core quantitative question directly. The survey had no BBN tool, so none of its Yp or D/H statements are computed. The server's validity range and data sets must be established before any of its numbers are trusted.

2. Quantify the X-ray decay-line constraints. Compute predicted line energies and fluxes with the server, then compare them with published 2024-2026 limits from NuSTAR, INTEGRAL/SPI, Chandra, eROSITA and XRISM to bound sin^2 2theta as a function of m_s. — X-ray limits provide the upper bound on mixing that, combined with the abundance and BBN results, defines the viable window. The decay-rate formula and the J-factor conversion need an independent check.

3. Survey the 2024-2026 production-mechanism literature (Shi-Fuller resonant production with lepton asymmetry, reheating production, scalar decays) and test its viability claims against tool-computed BBN numbers, adding the Lyman-alpha and structure-formation bounds. — Non-resonant production appears excluded, so the surviving region depends on resonant or non-oscillation mechanisms. Their BBN-compatibility claims must be checked numerically, and the arXiv IDs from the survey need verification.

4. Synthesize the d-01 BBN and relic-density results, the d-02 X-ray limits and the d-03 structure-formation bounds into a single table of viable (m_s, sin^2 2theta) regions per production mechanism, with an explicit provenance and robustness check. — No direction combines the constraints into the answer the task asks for. Without a synthesis step, claims about viable regions risk mixing tool-computed numbers with abstract-level claims. (added by the critic) Critic's view: revise — For keV-scale DM at sin^2 2theta below about 1e-8, the extra radiation from non-resonant production is negligible (Delta N_eff << 0.1). Yp and D/H shifts will then be indistinguishable from SBBN, and the BBN constraint is effectively vacuous in the region of interest. The direction must establish this from the tool output and say so explicitly. Without lepton asymmetry, BBN bites only at large mixing or low mass. Do not present a trivial BBN pass as a non-trivial constraint.; Set the scan ranges after describe_sterile_nu_tools reports the validity range, not before. Also run one zero-mixing (SBBN) baseline point, so that Yp and D/H deviations are reported both against the code's own SBBN value and against observation. This separates a code offset from a sterile-neutrino effect.; Budget risk: scan, plot, grid, bbn_impact, SBL check, DW checks and skill loading together approach 15 calls. Drop or defer check_sterile_nu_sbl_anomaly.

The eV-scale SBL point is not keV dark matter and is tangential to the task. Merge the DW-scaling checks into the predict_sterile_nu_grid call..

Wave 1 — now exploring, in parallel: Use the sterile-neutrino server to compute BBN observables (Yp, D/H, Delta N_eff) together with relic-density constraints across the (m_s, sin^2 2theta) plane. Identify which regions BBN and abundance arguments leave open.; Quantify the X-ray decay-line constraints. Compute predicted line energies and fluxes with the server, then compare them with published 2024-2026 limits from NuSTAR, INTEGRAL/SPI, Chandra, eROSITA and XRISM to bound sin^2 2theta as a function of m_s.; Survey the 2024-2026 production-mechanism literature (Shi-Fuller resonant production with lepton asymmetry, reheating production, scalar decays) and test its viability claims against tool-computed BBN numbers, adding the Lyman-alpha and structure-formation bounds..

Finding: All four survey arXiv IDs resolve: 2507.18752 (Vogel, Garcia Escudero, Froustey, Abazajian 2025, Shi-Fuller revival), 2502.17374 (Gorbunov, Kalashnikov, Krugan 2025, flavor-dependent asymmetry), 2601.03346 (Cline & Xu 2026, reheating/inflaton-decay production with BR <~ 1e-4) and 2609.31340 (Gorbunov & Kalashnikov 2026, saturation of resonant production at high flavor asymmetry); so q-03 is answered: 2609.31340 is a real paper.

Finding: 2507.18752 (full text) states: L >~ 0.5 at high T opens viable space at m_s >~ 10 keV and sin^2(2theta) <~ 1e-14; structure bounds used are m_th > 8.4 keV (galaxy counts, 95% CL), m_th > 8.5 keV (counts + strong lensing), and a Lyman-alpha preference m_th = 4.1 (+33.3/-1.5) keV; NuSTAR gives sin^2(2theta) <~ 1e-12 for 6-40 keV and INTEGRAL/SPI gives sin^2(2theta) <~ 3e-14 for m_s >~ 40 keV (lifetimes < ~1e20 s excluded).

Finding: The sterile-nu server cannot directly test the 2507.18752 claim. Its SF mode caps lepton_asymmetry at 0.1 (the paper needs L >~ 0.5), its SF Delta N_eff is a heuristic (0.1 x the DW value), and the asymmetry is not fed into the BBN network. At m_s = 10, 20, 30 keV with sin^2(2theta) = 1e-14 it gives Delta N_eff ~ 1e-8 and BBN Delta chi^2 = 0 (allowed). At 20 keV the outputs are Yp = 0.24682 and D/H = 2.4433e-5. Its SF Omega_s h^2 values are 0.122, 0.490, 1.10 for L = 1e-3 and 1.22, 4.90, 11.0 for L = 0.1 (10x larger for 100x larger L). All of these points are flagged as overclosing.

Finding: Mechanism map (from literature quotes, not computed by tools). Shi-Fuller resonant production with L >~ 0.5 above 20 MeV is viable at m_s >~ 10 keV and sin^2(2theta) <~ 1e-14 (2507.18752). Its X-ray ceilings are NuSTAR sin^2(2theta) <~ 1e-12 at 6-40 keV and SPI <~ 3e-14 above 40 keV. Its structure-formation bounds are m_th > 8.4-8.5 keV (galaxy counts and lensing) or the Lyman-alpha preference m_th ~ 4.1 keV. Flavor-dependent asymmetries, which work best with inverted ordering, open lower mixing angles and give colder spectra that reopen lighter m_s (2502.17374, abstract only). Large L saturates resonant production, which leaves about a two-decade window in sin^2(2theta) (2609.31340, abstract only). Inflaton-decay reheating production with BR <~ 1e-4 gives cold DM at mixings below the X-ray limits, which oscillation production cannot populate (2601.03346, abstract only).

Finding: The server's radiative decay rate agrees with Gamma = 1.38e-32 s^-1 (sin^2 2theta/1e-10)(m_s/keV)^5 to within about 1.5%. At m_s = 7.1 keV and sin^2 2theta = 1e-10 the tool gives 2.46e-28 s^-1 (formula 2.49e-28) with E_line = 3.55 keV. At 20 keV and 1e-12 it gives 4.36e-28 s^-1 (formula 4.42e-28) with E_line = 10 keV. The tool's built-in X-ray limits (NuSTAR M31, Roach+2020; XMM blank sky, Dessert+2020) exclude both points.

Finding: DW benchmark grid (m_s = 7.1, 10, 20, 50 keV; sin^2 2theta = 1e-10, 1e-12, 1e-14): no point is BBN-excluded (Delta N_eff <= 2.9e-3, |Delta chi^2| <= 0.04). DW Omega_s h^2 reaches 0.12 only near sin^2 2theta ~ 1e-10 at m_s ~ 10-20 keV (0.087 at 10 keV; 0.30 at 20 keV, which overcloses), and 50 keV at 1e-10 gives 1.58. At X-ray-allowed mixings of 1e-12 to 1e-14, DW gives Omega_s h^2 <= 0.016, so a non-DW mechanism is needed.

Completed — Survey the 2024-2026 production-mechanism literature (Shi-Fuller resonant production with lepton asymmetry, reheating production, scalar decays) and test its viability claims against tool-computed BBN numbers, adding the Lyman-alpha and structure-formation bounds.. All four arXiv IDs resolve to real papers (f-001): 2507.18752 (Vogel et al. 2025), 2502.17374 (Gorbunov, Kalashnikov and Krugan 2025), 2601.03346 (Cline and Xu 2026) and 2609.31340 (Gorbunov and Kalashnikov 2026). So 2609.31340 is genuine and q-03 is answered. I read the full text of 2507.18752, cited it in runs/261021_110150/references.bib and saved the text as runs/261021_110150/2507.18752.txt (f-002). The paper's viable region is m_s >~ 10 keV and sin^2(2theta) <~ 1e-14 for L >~ 0.5 at T > 20 MeV. Its bounds: NuSTAR sin^2(2theta) <~ 1e-12 at 6-40 keV, INTEGRAL/SPI <~ 3e-14 above 40 keV, m_th > 8.4 keV from galaxy counts, m_th > 8.5 keV from counts plus lensing, and a Lyman-alpha preference m_th = 4.1 (+33.3/-1.5) keV. Tool tests (f-003; CSVs sterile_nu_grid_SF_fdf543.csv and sterile_nu_grid_SF_d81486.csv) at m_s = 10, 20 and 30 keV with sin^2(2theta) = 1e-14 in SF mode give Delta N_eff ~ 1e-8 and BBN Delta chi^2 = 0 (allowed). At 20 keV Yp = 0.24682 and D/H = 2.4433e-5. Omega_s h^2 is 0.122, 0.490 and 1.10 at L = 1e-3 and ten times larger at L = 0.1; all of these points are flagged as overclosing. The tool cannot test the paper's claims. Its L is capped at 0.1 while the paper needs L >~ 0.5. Its SF Delta N_eff is a heuristic (0.1 x the DW value). It does not feed a xi_e effect into Yp, so the |xi_e| <~ 0.03 condition cannot be checked. Its SF Omega_s h^2 is not a Boltzmann calculation, so the overclosure flag does not contradict the paper. The BBN 'allowed' verdict is trivially true rather than supporting evidence. The server uses Yp = 0.2449 +/- 0.004 and D/H = 2.547 +/- 0.025 (relevant to q-02). Mechanism map (f-004) from the 2502.17374, 2609.31340 and 2601.03346 abstracts only: flavor-dependent asymmetries reopen lighter masses and smaller mixings; large L saturates resonant production, leaving about a two-decade window in sin^2(2theta); inflaton-decay reheating production with BR <~ 1e-4 populates cold DM below the X-ray limits. The survey criteria are only partly met. The full text of 2502.17374 was not read, so its viable ranges have no verbatim quotes. The 2024+ structure-formation search found only arXiv:2409.18917 (mixed WDM from Milky Way satellites), which was neither read nor cited. Open question q-07 asks for a BBN code that accepts xi_e, which a real test would need.

Finding: Sterile-nu server assumptions: BBN abundances come from a fit to PRyMordial (<0.3%), and the only BBN input is Delta N_eff. The fit is valid for N_eff in [2.044, 6.044], omega_b h^2 in [0.019, 0.0257] and tau_n in [866.4, 890.4] s, and for m_s below ~100 keV. For m_s >= 1 MeV, decay injection is not modelled, so those results are not constraints. Mechanisms are DW (non-resonant) and SF (resonant), where SF Delta N_eff is a heuristic (0.1 x DW) and SF relic density is a fitting formula in L. Observational values are Yp = 0.2449 +/- 0.004 (Aver+ 2021), D/H = (2.547 +/- 0.025)e-5 (Cooke+ 2018) and Planck N_eff = 2.99 +/- 0.17. Exclusion rule: Delta chi^2 vs SM > 3.84.

Finding: DW scan (m_s 1-100 keV, sin^2 2theta 1e-15 to 1e-6, 100x100 grid): BBN (Delta chi^2 > 3.84) excludes only sin^2 2theta above 3.5e-7 (1 keV), 1.2e-7 (3.7 keV), 8.1e-8 (7 keV), 4.3e-8 (13.5 keV), 1.5e-8 (50 keV) and 1e-8 (100 keV). The Omega_s h^2 = 0.12 contour lies at sin^2 2theta = 8.7e-9 (1 keV), 2.5e-9 (2 keV), 1.2e-9 (3 keV), 4.8e-10 (5 keV), 2.55e-10 (7.1 keV), 1.37e-10 (10 keV), 3.9e-11 (20 keV), 7.6e-12 (50 keV) and 2.2e-12 (100 keV), where Delta N_eff = 1e-4 to 1.1e-2 and |Delta chi^2_BBN| < 0.15. So the overclosure bound is 40x (1 keV) to 5000x (100 keV) stronger than BBN, and BBN leaves the whole DW DM line and everything below it open.

Finding: Tool-computed BBN at representative DW points, compared with the brief's Yp = 0.245 +/- 0.003 and D/H = (2.53 +/- 0.03)e-5. SM (N_eff = 3.044): Yp = 0.246815 (+0.6 sigma), D/H = 2.4433e-5 (-2.9 sigma). 7.1 keV, sin^2 2theta = 3e-10: Yp = 0.24684, D/H = 2.4440e-5, Delta chi^2 = -0.024 (shift from SBBN negligible). 1 keV, 3e-7: Delta N_eff = 0.387, Yp = 0.25193 (+2.3 sigma), D/H = 2.5718e-5 (+1.4 sigma), Delta chi^2 = +0.44, allowed. 10

keV, 1e-7: Delta N_eff = 0.813, Yp = 0.25730 (+4.1 sigma), D/H = 2.7145e-5 (+6.2 sigma), Delta chi^2 = 13.4, excluded. 3 keV, 3e-7: Delta N_eff = 0.931, Yp = 0.25874 (+4.6 sigma), D/H = 2.7540e-5 (+7.5 sigma), Delta chi^2 = 19.3, excluded. The BBN-only limit is Delta N_eff < 0.548 (95%), with slopes dYp/dN_eff = 0.0135 and dD/H(1e-5)/dN_eff = 0.331.

Finding: BEST cross-check (m_s = 1.14 eV, sin^2 2theta = 0.42): the server gives Delta N_eff = 1 (N_eff = 4.044), Yp = 0.25956, D/H = 2.777e-5 and Delta chi^2_BBN = 23.1 (excluded). That is 6.2 sigma tension with Planck N_eff = 2.99 +/- 0.17 and 33 sigma at CMB-S4. Omega_s h^2 = 29.3 under DW.

Finding: The server's DW relic density scales as Omega_s h^2 = 0.1 (sin^2 2theta / 1e-9)(m_s / 3 keV)^1.8. Checks: 3 keV at 1e-9 gives 0.100, 10 keV at 1e-9 gives 0.873 (ratio 8.73 = (10/3)^1.8), and 1 keV at 1e-8 gives 0.138. So the exponent 1.8 matches the brief's formula, but the normalization is 3x higher than the brief's 0.1 (sin^2 2theta / 3e-9)(m_s / 3 keV)^1.8, and the server's DM line sits at 3x smaller mixing.

Finding: XRISM Resolve stacked 3.75 Ms of data on ten galaxy clusters (arXiv:2510.24560, 2025) and found no unidentified lines over 2.5-15 keV. Its 3-sigma upper limit on the decay rate of an m_s ~ 7.1 keV particle (E = 3.55 keV) is Gamma ~ 1.0e-27 s^-1. That is 3-4 times stronger than the Hitomi Perseus limit but still 5 times above the rate implied by the Bulbul+2014 XMM detection, so XRISM does not yet rule out the 3.55 keV line. Scaling the server's rate (2.46e-28 s^-1 at sin^2 2theta = 1e-10) gives sin^2 2theta < ~4e-10 at 7.1 keV from XRISM alone.

Finding: Krivonos, Barinov, Mukhin and Gorbunov (arXiv:2405.17861, 2024) use 11 years of NuSTAR stray-light data on the Milky Way. They set 95% CL upper limits on sin^2 2theta for m_s ~ 6-40 keV (photon energies 3-20 keV), plotted in their Fig. 3 over the axis range 1e-15 to 1e-10 for several DM profiles. They state that the limits 'reach the bottom edge of theoretical predictions' of realistic production models. Their Eq. 2, Gamma = 1.36e-22 (m_s/keV)^5 sin^2 2theta s^-1, is 1.4% below the lead's 1.38e-32 normalisation and about 1% above the server's output.

Completed — Use the sterile-neutrino server to compute BBN observables (Yp, D/H, Delta N_eff) together with relic-density constraints across the (m_s, sin^2 2theta) plane. Identify which regions BBN and abundance arguments leave open.. Direction d-01 is complete: BBN rules out none of the parameter space that Dodelson-Widrow (DW, non-resonant) dark matter actually occupies; only overclosure does. All runs were local.

(1) Server limits and assumptions (f-007): Yp, D/H and Li7 come from a fit to the PRyMordial BBN network (<0.3% error), and the only BBN input is Delta N_eff. The fit is valid for N_eff 2.044-6.044, omega_b h^2 0.019-0.0257, tau_n 866.4-890.4 s and m_s below about 100 keV. At m_s >= 1 MeV, decay injection is not modelled, so those results are not constraints. Mechanisms are DW and Shi-Fuller (SF, resonant). The SF Delta N_eff is a heuristic (0.1 x DW) and the SF relic density is a fitting formula in the lepton asymmetry L. The server's data are Yp = 0.2449 +/- 0.004, D/H = (2.547 +/- 0.025)e-5 and Planck N_eff = 2.99 +/- 0.17, not the brief's values. A point is excluded when its BBN Delta chi^2 versus the SM exceeds 3.84 (95%). This answers q-01 and q-02.

(2) DW scan, m_s 1-100 keV x sin^2 2theta 1e-15 to 1e-6, 100x100 points (f-008): the files are scan_DW_dc7743.npz and .csv, and the exclusion plot is exclusion_scan_DW_dc7743.png (Figure 8). BBN excludes only large mixing: sin^2 2theta above 3.5e-7 at 1 keV, 1.2e-7 at 3.7 keV, 8.1e-8 at 7 keV, 4.3e-8 at 13.5 keV, 1.5e-8 at 50 keV and 1e-8 at 100 keV. From grid sterile_nu_grid_DW_360bc1.csv, the Omega_s h^2 = 0.12 line sits at sin^2 2theta = 8.7e-9 (1 keV), 2.5e-9 (2 keV), 1.2e-9 (3 keV), 4.8e-10 (5 keV), 2.55e-10 (7.1 keV), 1.37e-10 (10 keV), 3.9e-11 (20 keV), 7.6e-12 (50 keV) and 2.2e-12 (100 keV). Along that line Delta N_eff is 1e-4 to 1.1e-2 and |Delta chi^2| < 0.15. The overclosure bound is therefore 40x (1 keV) to about 5000x (100 keV) stronger than BBN. BBN leaves the whole DW dark-matter line and everything below

it open, so viability must be decided by the X-ray and Lyman-alpha bounds (d-02, d-03).

(3) Representative points from grid sterile_nu_grid_DW_397ef0.csv (f-009). Sigma values are against Yp = 0.245 +/- 0.003 and D/H = (2.53 +/- 0.03)e-5:

- SM: Yp = 0.246815 (+0.6 sigma), D/H = 2.4433e-5 (-2.9 sigma).
- 7.1 keV, 3e-10: Yp = 0.24684, D/H = 2.4440e-5. The shift from SBBN is negligible.
- 1 keV, 3e-7: Delta N_eff = 0.387, Yp = 0.25193 (+2.3 sigma), D/H = 2.5718e-5 (+1.4 sigma), Delta chi^2 = 0.44. Allowed.
- 10 keV, 1e-7: Delta N_eff = 0.813, Yp = 0.25730 (+4.1 sigma), D/H = 2.7145e-5 (+6.2 sigma), Delta chi^2 = 13.4. Excluded.
- 3 keV, 3e-7: Delta N_eff = 0.931, Yp = 0.25874 (+4.6 sigma), D/H = 2.754e-5 (+7.5 sigma), Delta chi^2 = 19.3. Excluded. From bbn_vs_neff.png (Figure 6), BBN alone gives Delta N_eff < 0.548 (95%), with dYp/dN_eff = 0.0135 and d(D/H x 1e5)/dN_eff = 0.331.

(4) BEST cross-check, 1.14 eV and sin^2 2theta = 0.42 (f-010): Delta N_eff = 1, Yp = 0.25956, D/H = 2.777e-5, Delta chi^2 = 23.1 (excluded). That is a 6.2 sigma tension with Planck and would be 33 sigma at CMB-S4.

(5) DW scaling check (f-011): the server gives Omega_s h^2 = 0.1 (sin^2 2theta / 1e-9)(m_s / 3 keV)^1.8. Its 1.8 exponent matches the brief, but its normalization is 3x higher than the brief's formula with 3e-9. As a result the server's dark-matter line sits at 3x smaller mixing, which d-02 needs to account for.

Caveats: the BBN numbers come from a fit, not a full network run. The SF mode was not scanned in this direction. The server cannot constrain masses of 1 MeV or more. All files are in /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261021_110150.

Completed — Quantify the X-ray decay-line constraints. Compute predicted line energies and fluxes with the server, then compare them with published 2024-2026 limits from NuSTAR, INTEGRAL/SPI, Chandra, eROSITA and XRISM to bound sin^2 2theta as a function of m_s.. Partly done: the decay-rate check and the 3.55 keV line status are complete, but the table of X-ray limits versus mass is not. (1) Decay-rate check (f-005; tc-...-25, tc-...-27): the server's rate matches Gamma = 1.38e-32 s^-1 (sin^2 2theta/1e-10)(m_s/keV)^5 to within about 1.5%. At m_s = 7.1 keV and sin^2 2theta = 1e-10 the tool gives 2.46e-28 s^-1 (formula 2.49e-28), with E = 3.55 keV and lifetime 4.07e27 s. At 20 keV and 1e-12 it gives 4.36e-28 s^-1 (formula 4.42e-28), with E = 10 keV. The rate normalisation in arXiv:2405.17861 Eq. 2 (1.36e-32 s^-1 at sin^2 2theta = 1e-10 and 1 keV) falls in the same range. Whole-halo fluxes at 7.1 keV and 1e-10 are 4.68 ph/s/cm^2 for the Milky Way centre, 6.89e-4 for M31 and 3.55e-5 for Perseus (f_DM = 1, no field-of-view cut). The tool's built-in NuSTAR M31 (Roach+2020) and XMM blank-sky (Dessert+2020) limits exclude both test points. (2) DW benchmark grid at 4 masses x 3 mixings (f-006; CSV /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261021_110150/sterile_nu_grid_DW_5199ae.csv): no point is BBN-excluded (Delta N_eff <= 2.9e-3). Omega_s h^2 is 0.087 at 10 keV and 1e-10, 0.30 at 20 keV and 1e-10 (overcloses), and 1.58 at 50 keV and 1e-10 (overcloses). At mixings of 1e-12 to 1e-14, Omega_s h^2 <= 0.016, so a non-DW mechanism is needed. Only the 1e-10 mixing was run through the X-ray tool at 7.1 keV, and only 1e-12 at 20 keV. (3) Status of the 3.55 keV line (f-012, cited in references.bib under key arxiv251024560): XRISM Resolve stacked ten clusters for 3.75 Ms (arXiv:2510.24560) and found no unidentified lines. Its 3-sigma limit is Gamma ~ 1.0e-27 s^-1 at

m_s ~ 7.1 keV, 3-4 times stronger than Hitomi but still 5 times above the Bulbul+2014 XMM signal, so the line is constrained but not ruled out. Scaling the tool's rate turns this into sin^2 2theta < ~4e-10. (4) NuSTAR 11-year stray-light limits (arXiv:2405.17861, Fig. 3, 95% CL, m_s ~ 6-40 keV; f-013) reach the lower edge of resonant-production predictions, but the numbers at 7, 10 and 20 keV were not read off the figure. Open items: the table of sin^2 2theta limits at 7, 10, 20 and 50 keV has no figure-read values yet (q-08). Searches for 2024-2026 eROSITA and INTEGRAL/SPI limits found nothing (dead end x-01). The XRISM-derived limit at 7.1 keV is the only quoted entry; 10, 20 and 50 keV need Fig. 3 of 2405.17861 and an SPI or NuSTAR GC source. The NuSTAR paper was not added to the bib.

Critic, wave 1 — continue: 9 findings stand up to the evidence, 4 questioned ('2507.18752 (full text) states: L >~ 0.5 at high T opens viable space at m_s >~ 10 keV and ': The quoted evidence is a download confirmation (tc-...-30) and characters 0-9000 of the paper (tc-...-37), which show only the title, authors and affiliations. None of the claimed numbers appear in the quoted excerpts: L >~ 0.5, m_s >~ 10 keV, sin^2 2theta <~ 1e-14, m_th > 8.4/8.5 keV, m_th = 4.1 (+33.3/-1.5) keV, NuSTAR 1e-12, SPI 3e-14. They may appear later in the 62k-character file, but the cited excerpts do not contain them.; 'Mechanism map (from literature quotes, not computed by tools). Shi-Fuller resonant product': The 2507.18752 numbers depend on the unevidenced f-002. Several specifics are not in the truncated abstracts quoted: the inverted-ordering preference and 'colder spectra' for 2502.17374, and the 'about two-decade window in sin^2 2theta' for 2609.31340. tc-...-51 is a pre-2024 review listing and supports none of these details.; 'XRISM Resolve stacked 3.75 Ms of data on ten galaxy clusters (arXiv:2510.24560, 2025) and ': tc-...-61 is an affiliations chunk (characters 9000-14000) and tc-...-62 is only a citation confirmation. Neither contains the 3.75 Ms exposure, the 2.5-15 keV band, Gamma ~ 1.0e-27 s^-1, the comparison with Hitomi or the comparison with Bulbul+2014. Only the final scaling (1e-27 / 2.46e-28 = 4.1, giving about 4e-10) can be checked, and it is correct given those inputs.; 'Krivonos, Barinov, Mukhin and Gorbunov (arXiv:2405.17861, 2024) use 11 years of NuSTAR str': The excerpts (title page and methods text on CXB fitting) do not contain Eq. 2, the Fig. 3 axis range or the 'bottom edge of theoretical predictions' quote. The claim also has an arithmetic inconsistency. The server's rate implies a coefficient of 2.46e-28 / (7.1^5 x 1e-10) = 1.36e-32, so the paper's 1.36e-32 matches the server to within about 0.3% rather than sitting 1% above it. The quoted '1.36e-22' also mis-transcribes the exponent.).

Issues: The DW normalization ambiguity decides the DW verdict at 7.1 keV. The server's DM line is at 2.55e-10. The brief's formula gives about 7.6e-10. The XRISM-only limit is about 4e-10. So DW at 3.5 keV is allowed under one normalization and excluded under the other. Neither normalization has been checked against a published DW production calculation, including its QCD-era uncertainty.; The SM D/H baseline (2.4433e-5) is 2.9 sigma below the brief's value and about 4 sigma below the server's 2.547 +/- 0.025. Because exclusion uses Delta chi^2 relative to the SM, extra radiation partly improves the D/H fit. This is why 1 keV at 3e-7 (Yp at +2.3 sigma) has Delta chi^2 of only 0.44. The Delta N_eff < 0.548 bound is therefore sensitive to the nuclear-rate choice and the baseline. This does not change the DW conclusion, but it matters for resonant-production claims.; The core deliverable, sin^2 2theta limits as a function of m_s, is missing at 10, 20 and 50 keV. NuSTAR Fig. 3 values were not read. No INTEGRAL/SPI or eROSITA 2024-2026 limit was sourced. The only number entering the viability table relies on the unevidenced f-002, so the viable region cannot yet be stated quantitatively from verified sources..

Next steps after wave 1 — One wave and 23 tool calls remain, so the plan uses two focused directions of about 11 calls each rather than three. I close d-04 because a synthesis run before verification would only restate the contested numbers. Its table becomes the final step of the first direction, which first re-supports f-002, f-012 and f-013 with verbatim quotes and fills the missing X-ray limits at 10-50 keV, the critic's top issue. The second direction resolves the

DW normalization ambiguity, which decides the 7.1 keV verdict, and adds m_th along the DW line so the structure-formation exclusion is actually quantified. The critic's BBN-robustness suggestion is folded into the second direction as a short analytic check rather than run as a separate direction, to stay within budget. The tools cannot test resonant production at L >~ 0.5, so those claims stay literature-sourced and are labelled that way. The task does not require a facility run, so none is scheduled.

New lines of investigation: Re-extract the quantitative literature claims (f-002, f-012, f-013) as verbatim quotes. Build a verified X-ray limit table at m_s = 7.1, 10, 20, 40 and 50 keV. Then produce the final per-mechanism viability table in the (m_s, sin^2 2theta) plane (DW, Shi-Fuller with lepton asymmetry, flavor-dependent asymmetry, reheating production), with a provenance column for each entry.; Settle the factor-3 DW relic-density normalization against a published calculation and compute m_th along the DW dark-matter line. Also give a short BBN robustness check: the Delta N_eff bound under the brief's data versus the server's data, and the joint (Delta N_eff, xi_e) bound using dYp/dxi_e ~ -0.25..

Wave 2 — now exploring, in parallel: Re-extract the quantitative literature claims (f-002, f-012, f-013) as verbatim quotes. Build a verified X-ray limit table at m_s = 7.1, 10, 20, 40 and 50 keV. Then produce the final per-mechanism viability table in the (m_s, sin^2 2theta) plane (DW, Shi-Fuller with lepton asymmetry, flavor-dependent asymmetry, reheating production), with a provenance column for each entry.; Settle the factor-3 DW relic-density normalization against a published calculation and compute m_th along the DW dark-matter line. Also give a short BBN robustness check: the Delta N_eff bound under the brief's data versus the server's data, and the joint (Delta N_eff, xi_e) bound using dYp/dxi_e ~ -0.25..

Finding: f-002 re-supported verbatim from 2507.18752 full text: "lepton asymmetries L?0.5 at high temperatures open significant viable parameter space in the m_s?10 keV and sin^2(2θ)?10^-14 regime, compatible with both x-ray constraints from NuSTAR and INTEGRAL/SPI and recent Lyman-α inferences of m_th≈4.1 keV"; X-ray: "set 95% CL upper limits at sin^2(2θ)?10^-12 in the 6–40 keV mass range" (NuSTAR) and SPI "exclude lifetimes below ∼10^20 s at 95% CL [corresponding to sin^2(2θ)?3×10^-14] in the ?40 keV mass regime"; structure: "m_th > 8.4 keV (95% CL) [18] for galaxy counts, m_th > 8.5 keV (95% CL) from a combination of galaxy counts and strong lensing" and Lyman-alpha "m_th = 4.1+33.3-1.5 keV".

Finding: f-012 re-supported verbatim from XRISM 2510.24560 abstract: "We stack 3.75 Megaseconds of early XRISM Resolve observations of ten galaxy clusters to search for unidentified spectral lines in the E= 2.5-15 keV band (rest frame)... No unidentified lines are detected... with the 3σ upper limit on the m_s∼7.1 keV DM particle decay rate (which corresponds to a E= 3.55 keV emission line) of Γ∼1.0×10^-27 s^-1. This upper limit is 3-4 times lower than the one derived by Hitomi ... but still 5 times higher than the XMM-Newton detection reported by Bulbul et al. (2014)". With Γ = 1.38e-32 (sin^2 2θ/1e-10)(m_s/keV)^5 s^-1 this converts to sin^2 2θ < ~4e-10 at 7.1 keV (3σ, cluster J-factors as in the paper; derived, not quoted).

Finding: f-013 partially re-supported, but the requested figure readings were not obtained. Verbatim from 2405.17861: Eq. 2 reads "$\Gamma\gamma$ = 9/1024 α/π^4 G_F^2 m_s^5 sin^2 2θ = 1.36×10^-22 (m_s/1keV)^5 sin^2 2θ s^-1". The exponent -22 is correct as written, because sin^2 2θ is not normalized there; it equals 1.36e-32 s^-1 at sin^2 2θ = 1e-10, so the board's "correction to 1e-32" applies only to the normalized form. The paper places "new upper limits on the active-sterile mixing angle θ for sterile neutrino masses m_s = 6-40 keV" at 95% CL. Fig. 3 is plotted on a sin^2(2θ) axis from 1e-15 to 1e-10. The paper says that observed limits are "stronger ... in certain mass ranges (e.g. m_νs = 8-9 keV or 23-25 keV)", and that "the borderline excess at 40 keV is the known instrumental effect". I could not read numerical values at 7, 10 or 20 keV: Fig. 3 is missing from the HTML rendering, and the Fig. 1 image (registered as Figure 15) was downloaded but cannot be digitized with the available tools. So the only NuSTAR number per mass is the secondary 2507.18752 summary, sin^2 2θ <~ 1e-12 across 6-40

keV.

Finding: X-ray limit table (95% CL unless noted), each limit cross-checked with the server's line tool:

- 7.1 keV: XRISM gives Gamma < 1.0e-27 s^-1 at 3 sigma, which converts to sin^2 2θ < ~4e-10 (quote in f-015). NuSTAR gives <~1e-12 over 6-40 keV (2507.18752 quote). The tool's built-in tables exclude the point 1e-10 (tc-...-d-02-25).
- 10 keV: NuSTAR <~1e-12. The tool gives Gamma = 1.36e-29 s^-1, E = 5 keV and lifetime 7.35e28 s at 1e-12, which its tables do not exclude.
- 20 keV: NuSTAR <~1e-12. The tool's tables exclude 1e-12 (tc-...-d-02-27), so its NuSTAR M31 table is stronger than the summary value here.
- 40 keV: NuSTAR's 6-40 keV upper edge, where 2405.17861 flags an instrumental excess, and SPI at >~40 keV gives <~3e-14.
- 50 keV: SPI <~3e-14. The tool gives Gamma = 1.28e-27 s^-1, E = 25 keV and lifetime 7.84e26 s at 3e-14, not excluded. Warning: 2507.18752 equates SPI's "lifetimes below ~1e20 s" with sin^2 2θ <~ 3e-14, but the tool's lifetime at 3e-14 and 50 keV is 7.8e26 s. The lifetime and mixing in that quote are inconsistent by about 7 orders of magnitude, so the SPI mixing value should be checked against the primary SPI paper. No figure-read values from 2405.17861 were obtained at 7, 10 or 20 keV.

Finding: Final viability table in the (m_s, sin^2 2θ) plane:

- DW (non-resonant): not viable as all of the dark matter. The DM line sits at sin^2 2θ = 2.55e-10 (7.1 keV), 1.37e-10 (10 keV), 3.9e-11 (20 keV) and 7.6e-12 (50 keV) (server normalization, f-008). All of these lie above the XRISM limit (~4e-10 at 7.1 keV is the only point below the line's value there, but it sits within a factor of 1.6) and above the NuSTAR <~1e-12 and SPI <~3e-14 limits. Binding constraint: X-ray. BBN is not binding; Delta chi^2 < 0.15 along the line. Provenance: f-008 and f-014 to f-017. 2507.18752 states "the original DW mechanism is ruled out as producing the entirety of the dark matter".
- Shi-Fuller with L >~ 0.5 at T > 20 MeV: viable at m_s >~ 10 keV and sin^2 2θ <~ 1e-14. Binding constraints are X-ray (NuSTAR 1e-12, SPI 3e-14 above 40 keV) and structure formation (m_th > 8.4-8.5 keV from galaxy counts and lensing, against a Lyman-alpha preference of 4.1 keV). Provenance: verbatim quotes from 2507.18752 (f-014). Server BBN is trivially allowed (f-003), but this is not an independent test because the tool caps L at 0.1.
- Flavor-dependent asymmetry (2502.17374): lighter m_s at smaller mixing, with BBN limits weakened and colder spectra. Abstract only; no numerical ranges are quoted. Saturation at large L (2609.31340) leaves a window of about two decades in sin^2 2θ; abstract only.
- Reheating (inflaton decay, BR <~ 1e-4; 2601.03346): cold DM at mixings below the X-ray limits. Binding constraint: X-ray only. Abstract only.

Completed — Re-extract the quantitative literature claims (f-002, f-012, f-013) as verbatim quotes. Build a verified X-ray limit table at m_s = 7.1, 10, 20, 40 and 50 keV. Then produce the final per-mechanism viability table in the (m_s, sin^2 2theta) plane (DW, Shi-Fuller with lepton asymmetry, flavor-dependent asymmetry, reheating production), with a provenance column for each entry.. All three contested

findings now have verbatim quotes. The X-ray limit table covers five masses, but only one value is read directly from a primary source; the rest come from a secondary summary. Viability table: f-018. Findings f-014 to f-018 and dead end x-02 are posted.

(1) f-002, re-supported by f-014, quoting the 2507.18752 full text (runs/261021_110150/2507.18752.txt, tc-...-w2-d-05-72). Viable region: 'L?0.5 ... m_s?10 keV and sin^2(2θ)?10^-14'. NuSTAR: 'sin^2(2θ)?10^-12 in the 6–40 keV mass range'. INTEGRAL/SPI: 'exclude lifetimes below ∼10^20 s at 95% CL [corresponding to sin^2(2θ)?3×10^-14] in the ?40 keV mass regime'. Structure formation: m_th > 8.4 keV from galaxy counts, m_th > 8.5 keV from counts plus strong lensing, and a Lyman-alpha preference of m_th = 4.1 (+33.3/-1.5) keV.

(2) f-012, re-supported by f-015, quoting the 2510.24560 abstract (tc-...-84). XRISM stacked 3.75 Ms of data on ten clusters over 2.5-15 keV. Its 3-sigma limit is $\Gamma \sim$ 1.0e-27 s^-1 at m_s ∼ 7.1 keV, which converts to sin^2 2θ < ~4e-10 (my conversion, not a quote).

(3) f-013, partly re-supported and downgraded to medium by f-016 (tc-...-77, -80, -85). Eq. 2 of 2405.17861 reads 1.36×10^-22 (m_s/keV)^5 sin^2 2θ s^-1. That exponent is correct as written, because sin^2 2θ is not normalised there; it equals 1.36e-32 s^-1 at sin^2 2θ = 1e-10. The paper gives 95% limits for m_s = 6-40 keV, with observed limits stronger than expected at 8-9 and 23-25 keV and an instrumental excess at 40 keV. Fig. 3 is missing from the HTML rendering. The Fig. 1 image was downloaded (Figure 15, figures_2405.17861/fig01.png) but not read numerically. So the 7, 10 and 20 keV entries rest on the secondary summary value of <~1e-12. 2405.17861 is now cited in references.bib under arxiv240517861 (tc-...-96).

(4) X-ray limit table (f-017), cross-checked with the server's line tool:

- 7.1 keV: XRISM < ~4e-10 (3 sigma); NuSTAR <~1e-12.
- 10 keV: NuSTAR <~1e-12. At 1e-12 the tool gives Γ = 1.36e-29 s^-1, E = 5 keV and lifetime 7.35e28 s, not excluded by its tables (tc-...-95).
- 20 keV: NuSTAR <~1e-12. The tool's own tables exclude 1e-12 (d-02).
- 40 keV: the upper edge of NuSTAR coverage, where SPI <~3e-14 takes over.
- 50 keV: SPI <~3e-14. At 3e-14 the tool gives Γ = 1.28e-27 s^-1 and lifetime 7.8e26 s, not excluded (tc-...-94). Warning: the SPI quote equates a lifetime of ~1e20 s with a mixing of 3e-14, but the tool gives 7.8e26 s at that mixing, a gap of about 7 orders of magnitude. The SPI mixing value needs checking against the primary SPI paper. My search for a 2024-2026 SPI or NuSTAR limit above 40 keV found nothing (dead end x-02, tc-...-86).

(5) Viability table (f-018):

- Dodelson-Widrow: excluded as all of the dark matter. Its dark-matter line (2.55e-10 at 7.1 keV, 1.37e-10 at 10 keV, 3.9e-11 at 20 keV, 7.6e-12 at 50 keV; server normalisation from f-008) lies above the NuSTAR and SPI limits, so X-ray is the binding constraint and BBN is not. Correction to the wording in f-018: at 7.1 keV the dark-matter line (2.55e-10) sits below the XRISM limit (~4e-10), so XRISM alone does not exclude it there; NuSTAR does.
- Shi-Fuller with L >~ 0.5 at T > 20 MeV: viable at m_s >~ 10 keV and sin^2 2θ <~ 1e-14. The binding constraints are X-ray and m_th. Provenance is the 2507.18752 quotes; the server cannot test this because it caps L at 0.1.
- Flavor-dependent asymmetry (2502.17374) and saturation at large L (2609.31340): lighter masses at smaller mixing, and about a two-decade window in mixing. Abstract only.

- Reheating production (2601.03346, branching ratio <~ 1e-4): cold dark matter below the X-ray limits. Abstract only.

Finding: The published DW normalization (Abazajian 2017 review, arXiv:1705.01837 Eq. 37, a fit from Ref. [120]) is m_s ~ 3.40 keV (sin^2 2theta/1e-8)^-0.615 (Omega_DM/0.26)^0.5 x 0.527 erfc[-1.15 (T_QCD/170 MeV)^2.15]. Inverting it gives a DM line at sin^2 2theta ~ 1.23e-8 (3 keV), 3.0e-9 (7.1 keV), 1.73e-9 (10 keV), 5.6e-10 (20 keV) and 1.26e-10 (50 keV). The server line from the tool is 1.2e-9, 2.55e-10, 1.37e-10, 3.9e-11 and 7.6e-12 (Omega_s h^2 = 0.119-0.120). So the published line needs 10x (3 keV) to 17x (50 keV) more mixing than the server and 3.4-5.5x more than the brief's formula. The two differ in shape as well as normalization: Omega is proportional to m^2 (sin^2 2theta)^1.23 rather than m^1.8 times sin^2 2theta.

Finding: At 7.1 keV the DW verdict depends on the normalization when compared with the XRISM limit sin^2 2theta < ~4e-10 (f-012). The server line (2.55e-10) survives XRISM. The brief's line (7.65e-10) and the published Abazajian line (3.0e-9, about +10%/-7% from T_QCD) are excluded, the published one by about 7.5x. Since the published normalization is the reference calculation, DW dark matter at 7.1 keV is excluded by XRISM alone. The server's DW Omega_s h^2 underestimates the mixing needed by about 12x at 7.1 keV, so server-based DW statements are not conservative.

Finding: On the DW DM line, the standard DW-to-thermal mapping m_s = 4.43 keV (m_th/keV)^(4/3) (Viel et al. 2005, astro-ph/0501562; text downloaded, but the formula was not quoted verbatim from it) gives m_th = 0.75 keV (m_s = 3 keV), 1.42 keV (7.1 keV), 1.84 keV (10 keV), 3.10 keV (20 keV) and 6.16 keV (50 keV). Lyman-alpha m_th > 4 (6) keV requires m_s > 28 (48) keV, and satellite counts m_th > 8.4 keV require m_s > 76 keV. At m_s >= 28 keV the DW line has sin^2 2theta ~ 3e-10 (published normalization) or about 1e-11 (server). Both values lie far above the NuSTAR ceiling of about 1e-12 at 6-40 keV and the SPI ceiling of about 3e-14 above 40 keV (f-002). The surviving DW mass interval is therefore empty under all three normalizations.

Finding: BBN robustness check. I used linearized f-009 slopes (dYp/dN_eff = 0.0135, dD/H/dN_eff = 0.331e-5) about the server SM values (Yp = 0.246815, D/H = 2.4433e-5). The 95% upper bounds on Delta N_eff are given as Delta chi^2 = 3.84 against the SM, with Delta chi^2 = 3.84 against the best fit in brackets. Brief data (Yp 0.245 +/- 0.003, D/H 2.53 +/- 0.03): Yp-only 0.32; D/H-only 0.58 [0.44]; combined 0.47 [0.37]. Server data (Yp 0.2449 +/- 0.004, D/H 2.547 +/- 0.025): Yp-only 0.46; D/H-only 0.66 [0.46]; combined 0.61 [0.43]. The server tool reports 0.548. D/H alone prefers Delta N_eff = 0.26 (brief data) or 0.31 (server data) because the SM D/H sits 2.9 or 4.1 sigma low, so the bound depends on the baseline at the 0.1-0.2 level. Joint bound with dYp/dxi_e = -0.25, assuming D/H does not depend on xi_e, using 2-dof Delta chi^2 = 5.99. Brief data: Delta N_eff in [0.04, 0.48] and xi_e = 0.0073 + 0.054 Delta N_eff +/- 0.029. Server data: Delta N_eff in [0.13, 0.50] and xi_e = 0.0077 + 0.054 Delta N_eff +/- 0.039. So |xi_e| <~ 0.03-0.06 overall, and a positive xi_e of about 0.03 compensates Delta N_eff of about 0.5 in Yp.

Completed — Settle the factor-3 DW relic-density normalization against a published calculation and compute m_th along the DW dark-matter line. Also give a short BBN robustness check: the Delta N_eff bound under the brief's data versus the server's data, and the joint (Delta N_eff, xi_e) bound using dYp/dxi_e ~ -0.25.. Normalization (f-019): the published DW fit in arXiv:1705.01837 (Abazajian review) Eq. 37 is m_s ~ 3.40 keV (sin^2 2theta/1e-8)^-0.615 (Omega_DM/0.26)^0.5 x 0.527 erfc[-1.15 (T_QCD/170 MeV)^2.15]. It is cited in references.bib under key arxiv170501837. I inverted it by hand. Its dark-matter line sits at sin^2 2theta ~ 1.23e-8 (3 keV), 3.0e-9 (7.1 keV), 1.73e-9 (10 keV), 5.6e-10 (20 keV) and 1.26e-10 (50 keV). The QCD-era uncertainty (T_QCD 150-200 MeV) moves these by about +10%/-7%. The server line from predict_sterile_nu_grid (ster-

ile_nu_grid_DW_2461e9.csv, Omega h^2 = 0.119-0.120) is 1.2e-9, 2.55e-10, 1.37e-10, 3.9e-11 and 7.6e-12. The published normalization therefore needs 10-17x more mixing than the server and 3.4-5.5x more than the brief's formula, and it scales differently with mass and mixing. Verdict at 7.1 keV (f-020): against the XRISM limit of about 4e-10, the server line (2.55e-10) survives, while the brief's line (7.65e-10) and the published line (3.0e-9) are excluded. Using the published normalization, DW at 7.1 keV is excluded by about 7.5x. m_th (f-021): I used the DW-to-thermal mapping m_s = 4.43 keV (m_th)^(4/3) from Viel+2005 (astro-ph/0501562). I downloaded that paper but did not quote the coefficient verbatim from it. This gives m_th = 0.75, 1.42, 1.84, 3.10 and 6.16 keV at m_s = 3, 7.1, 10, 20 and 50 keV. Lyman-alpha (m_th > 4-6 keV) then needs m_s > 28-48 keV, and satellite counts (m_th > 8.4 keV) need m_s > 76 keV. At those masses the DW line under any of the three normalizations sits well above the NuSTAR (~1e-12) and SPI (~3e-14) ceilings, so the surviving DW mass interval is empty. BBN (f-022): these are analytic results from linearized f-009 slopes, not server runs. Upper bounds on Delta N_eff at 95%, relative to the SM: with the brief's data, 0.32 from Yp only, 0.58 from D/H only and 0.47 combined. With the server's data, 0.46, 0.66 and 0.61. The server tool itself quotes 0.548. The SM D/H sits 2.9-4.1 sigma low, so D/H prefers Delta N_eff ~ 0.3 and the bound moves by 0.1-0.2 depending on the baseline. For the joint bound I used dYp/dxi_e = -0.25 and 2-dof Delta chi^2 < 5.99. Brief data: Delta N_eff in [0.04, 0.48], with xi_e = 0.0073 + 0.054 Delta N_eff +/- 0.029. Server data: Delta N_eff in [0.13, 0.50], with xi_e = 0.0077 + 0.054 Delta N_eff +/- 0.039. Overall |xi_e| <~ 0.03-0.06. Question q-09 is posted. Open items: the Viel coefficient and the full Eq. 37 citation still need verbatim quotes, and dD/H/dxi_e was neglected.

Critic, wave 2 — continue: 5 findings stand up to the evidence, 4 questioned ('X-ray limit table (95% CL unless noted), each limit cross-checked with the server's line t': The tool values at 10 keV (Gamma 1.36e-29 s^-1, lifetime 7.35e28 s) and 50 keV (1.28e-27 s^-1, 7.84e26 s) match the excerpts. Two parts do not hold. (1) The 'not excluded' and 'excluded' verdicts at 10, 20 and 50 keV cannot be seen in the truncated excerpts. (2) The claimed 7-order inconsistency in the SPI quote is almost certainly a seconds-versus-years slip. The tool's own output at 50 keV and 3e-14 is 2.48e19 yr. Read as ~1e20 yr (3.2e27 s), the SPI lifetime matches sin^2 2theta ~2.3e-14 at 40 keV and ~7.5e-15 at 50 keV, which agrees with the quoted ~3e-14. The finding asserts a contradiction where the units are the more likely explanation.; 'Final viability table in the (m_s, sin^2 2θ) plane:

- DW (non-resonant): not viable as all': The claim says the DW line at all masses lies 'above the XRISM limit', but at 7.1 keV the server line (2.55e-10) is below ~4e-10. The d-05 summary corrects this, but the posted claim still contains it. The DW row is also built on the server normalization, which f-019 shows is 10-17x low. The Shi-Fuller row inherits the SPI ceiling of 3e-14, whose interpretation f-017 left open. The table should be reissued with the published DW line and the corrected XRISM wording.; 'The published DW normalization (Abazajian 2017 review, arXiv:1705.01837 Eq. 37, a fit from': The hand inversion is arithmetically correct. For example, 0.527*erfc(-1.15) = 0.999, giving 3.0e-9 at 7.1 keV and 1.26e-10 at 50 keV. However, the cited excerpt (tc-...-d-06-97, chars 46000-60000) shows Eq. 35 and the Fig. 2 lepton-asymmetry plot, not Eq. 37. No tool output on the board contains the quoted fit formula.; 'At 7.1 keV the DW verdict depends on the normalization when compared with the XRISM limit ': The verdict 'excluded by about 7.5x at 7.1 keV' depends entirely on the f-019 normalization, which is not yet evidenced. The XRISM evidence excerpt (tc-...-d-02-61) contains only author affiliations. The XRISM-to-mixing conversion (~4e-10) checks out arithmetically against the decay-rate formula.).

Issues: The SPI 'lifetime ~1e20 s' is very likely ~1e20 yr. The tool gives 2.48e19 yr at 50 keV

and 3e-14, and m_s^5 scaling puts 1e20 yr at ~2.3e-14 at 40 keV. Resolve this against the primary SPI paper rather than flagging a 7-order discrepancy. It sets the mass dependence of the ceiling above 40 keV, which tightens as m_s^-5, so 'flat 3e-14' is wrong at 50-100 keV.; All NuSTAR entries at 7-20 keV rest on a secondary 'flat <~1e-12 over 6-40 keV' summary. The real 2405.17861 curve varies with mass: it is stronger at 8-9 and 23-25 keV and has the 40 keV artefact. The fig01.png file exists and should be digitized, or the limits taken from the arXiv source or supplementary tables.; The f-014 and f-015 excerpts show only the title page and affiliations, not the quoted sentences. The quotes are consistent with prior findings and the arithmetic, but future findings should excerpt the relevant character range..

Stopping after wave 2: budget reached (2/2 waves used). Writing the report from the board.

Research report:

Sterile-neutrino dark matter in 2024-2026: combined BBN and X-ray viability of the (m_s, sin^2 2θ) plane

Abstract

This study surveyed recent arXiv work on keV sterile-neutrino dark matter. It combined tool-computed BBN observables (Yp, D/H, ΔN_eff) with published X-ray decay-line limits to identify which (m_s, sin^2 2θ) regions remain viable.

BBN is not a useful constraint on keV dark matter without a lepton asymmetry.

- Along the non-resonant Dodelson-Widrow (DW) dark-matter line, ΔN_eff is between 1e-4 and 1.1e-2, and the BBN $\Delta\chi^2$ relative to the Standard Model is below 0.15.
- The overclosure bound is 40 to about 5000 times stronger than BBN over 1-100 keV.

DW production cannot supply all of the dark matter.

- X-ray limits exclude it. These are NuSTAR, quoted as sin^2 2θ ? 1e-12 at 6-40 keV, and INTEGRAL/SPI, quoted as ? 3e-14 above 40 keV.
- Structure formation independently excludes the masses where DW could otherwise survive.
- At 7.1 keV the XRISM-only verdict depends on which DW relic normalization is used. The server's normalization differs from the published fit by a factor of 10-17 in mixing.

What survives requires non-oscillation production or very small mixing.

- Shi-Fuller resonant production with a lepton asymmetry L ? 0.5 at T > 20 MeV is quoted as viable at m_s ? 10 keV and sin^2 2θ ? 1e-14 (arXiv:2507.18752). The available server cannot test this: it caps L at 0.1.
- Flavor-dependent asymmetries and reheating production open further regions. Those claims rest on abstracts only.

Background

The main recent combined analysis is Vogel, Garcia Escudero, Froustey and Abazajian (arXiv:2507.18752, 2025), who revisit Shi-Fuller resonant production. The full text was read, and states:

- "lepton asymmetries L?0.5 at high temperatures open significant viable parameter space in the m_s?10 keV and sin^2(2θ)?10^-14 regime".
- That region is compatible with NuSTAR ("sin^2(2θ)?10^-12 in the 6–40 keV mass range").
- It is also compatible with INTEGRAL/SPI ("exclude lifetimes below ∼10^20 s at 95% CL [corresponding to sin^2(2θ)?3×10^-14] in the ?40 keV mass regime").
- The structure-formation bounds used are m_th > 8.4 keV (galaxy counts, 95% CL) and m_th > 8.5 keV (counts plus strong lensing). The paper also cites a Lyman-alpha preference of m_th = 4.1 (+33.3/-1.5) keV.
- The paper states that "the original DW mechanism is ruled out as producing the entirety of the dark matter".

Three further papers were confirmed to exist by metadata lookup. Only their abstracts were read, so their claims are reported here as abstract-level statements without numerical ranges:

- **Gorbunov, Kalashnikov and Krugan (arXiv:2502.17374, 2025).** Lepton asymmetry spread unequally over flavors can mitigate BBN limits on mixing and mass, through cancellation of flavor asymmetries. The brief notes this works best with inverted ordering. It gives colder spectra that reopen lighter masses.
- **Gorbunov and Kalashnikov (arXiv:2609.31340, 2026).** A high lepton flavor asymmetry saturates resonant production. The board's summary of the abstract is that this leaves a window of about two decades in sin^2 2θ. The concern that this ID was hallucinated is resolved: the paper is real.
- **Cline and Xu (arXiv:2601.03346, 2026).** Cold sterile-neutrino dark matter can be produced by inflaton decays during reheating, with branching ratio ? 1e-4. This populates mixings too small for oscillation production and below current X-ray limits.

On the X-ray side, two recent papers were found:

- **XRISM Resolve (arXiv:2510.24560).** This stacked 3.75 Ms on ten clusters over 2.5-15 keV and found no unidentified lines.
- **NuSTAR stray-light analysis (Krivonos, Barinov, Mukhin and Gorbunov, arXiv:2405.17861)** This used 11 years of data and set 95% CL limits for m_s = 6-40 keV.

Baseline references used:

- The Abazajian review (arXiv:1705.01837), for the published DW relic fit.
- Viel et al. (astro-ph/0501562), for the DW-to-thermal mass mapping.
- Merle (arXiv:1702.08430), as a pre-2024 review.

No citable arXiv source was found for 2024-2026 eROSITA or INTEGRAL/SPI line limits. The eROSITA statement in the brief came from a non-citable web snippet.

Results

Tool capabilities and assumptions The sterile-neutrino server computes Yp, D/H and Li7 from a fit to the PRyMordial BBN network, accurate to better than 0.3%. Its only BBN input is ΔN_eff.

Item	Server setting
N_eff validity range	2.044-6.044
ω_b h^2 validity range	0.019-0.0257
τ_n validity range	866.4-890.4 s
Mass validity	m_s below about 100 keV; at m_s $\geq$ 1 MeV decay injection is not modelled
Yp data	0.2449 $\pm$ 0.004 (Aver+ 2021)
D/H data	(2.547 $\pm$ 0.025)e-5 (Cooke+ 2018)
N_eff data	Planck 2.99 $\pm$ 0.17
Exclusion rule	$\Delta\chi^2 > 3.84$ relative to the SM

The server's data values differ from the brief's Yp = 0.245 $\pm$ 0.003 and D/H = (2.53 $\pm$ 0.03)e-5.

Two production modes are offered:

- **DW (non-resonant).**
- **Shi-Fuller (SF, resonant).** Its ΔN_eff is a heuristic set to 0.1 times the DW value, and its relic density is a fitting formula in L. The lepton asymmetry is not fed into the BBN network.

BBN versus the DW plane A 100 $\times$ 100 DW scan covered m_s = 1-100 keV and sin^2 2θ = 1e-15 to 1e-6. It showed that BBN excludes only large mixing.

m_s	BBN exclusion starts above sin^2 2θ =
1 keV	3.5e-7
3.7 keV	1.2e-7
7 keV	8.1e-8
13.5 keV	4.3e-8
50 keV	1.5e-8
100 keV	1e-8

The server's Ω_s h^2 = 0.12 contour lies far below these thresholds:

m_s (keV)	1	2	3	5	7.1	10	20	50	100
sin^2 2θ on DM line	8.7e-9	2.5e-9	1.2e-9	4.8e-10	2.55e-10	1.37e-10	3.9e-11	7.6e-12	2.2e-12

Along this line ΔN_eff is 1e-4 to 1.1e-2 and $|\Delta\chi^2$_BBN$| < 0.15$. Overclosure is therefore 40 times (1 keV) to about 5000 times (100 keV) stronger than BBN. The entire DW dark-matter line and everything below it are BBN-allowed.

[[FIGURE 8]]

Figure 8 shows the DW exclusion plot from this scan: the BBN-excluded region at large mixing and the overclosure region, in the (m_s, sin^2 2θ) plane.

Representative points are listed below, with σ values relative to the brief's data.

Point	ΔN_eff	Yp	D/H	Δχ^2	Verdict
SM, N_eff = 3.044	0	0.246815 (+0.6σ)	2.4433e-5 (-2.9σ)	0	baseline
7.1 keV, 3e-10	negligible	0.24684	2.4440e-5	-0.024	allowed
1 keV, 3e-7	0.387	0.25193 (+2.3σ)	2.5718e-5 (+1.4σ)	0.44	allowed
10 keV, 1e-7	0.813	0.25730 (+4.1σ)	2.7145e-5 (+6.2σ)	13.4	excluded
3 keV, 3e-7	0.931	0.25874 (+4.6σ)	2.7540e-5 (+7.5σ)	19.3	excluded

The 1 keV point is allowed despite Yp sitting at $+2.3\sigma$. The reason is that the SM D/H sits low, so extra radiation improves the D/H fit and offsets the Yp penalty.

[[FIGURE 6]]

Figure 6 shows the server's BBN response to N_eff. From it:

- BBN alone gives ΔN_eff < 0.548 at 95%.
- The slopes are dYp/dN_eff = 0.0135 and d(D/H × 1e5)/dN_eff = 0.331.

A separate server cross-check used the BEST short-baseline point (m_s = 1.14 eV, sin^2 2θ = 0.42). It gave:

- ΔN_eff = 1, Yp = 0.25956, D/H = 2.777e-5 and Δχ^2 = 23.1, so the point is excluded.
- 6.2σ tension with Planck N_eff, and 33σ at CMB-S4.

BBN robustness: data baseline and lepton asymmetry These are analytic results, not server runs. They linearize the slopes above about the server SM values. Bounds are 95% upper limits on ΔN_eff, with Δχ^2 = 3.84 against the SM; values in brackets are against the best fit.

Data set	Yp only	D/H only	Combined
Brief's data	0.32	0.58 [0.44]	0.47 [0.37]
Server's data	0.46	0.66 [0.46]	0.61 [0.43]

The server itself reports 0.548. Because the SM D/H is 2.9σ (brief) to 4.1σ (server) low, D/H alone prefers ΔN_eff ≈ 0.26-0.31. The bound therefore moves by 0.1-0.2 depending on the baseline.

The joint (ΔN_eff, ξ_e) bound used dYp/dξ_e = -0.25, assumed D/H independent of ξ_e, and applied 2-dof Δχ^2 = 5.99.

Data set	Allowed ΔN_eff	Allowed ξ_e
Brief's data	[0.04, 0.48]	$0.0073 + 0.054\,\Delta N_eff \pm 0.029$
Server's data	[0.13, 0.50]	$0.0077 + 0.054\,\Delta N_eff \pm 0.039$

Overall this gives |ξ_e| ? 0.03-0.06. A positive ξ_e of about 0.03 compensates a ΔN_eff of about 0.5 in Yp. Two caveats affect the ξ_e headroom available to Shi-Fuller scenarios:

- The SM D/H baseline depends on the choice of d(p,γ)3He rate.
- Neglecting dD/H/dξ_e biases the joint contour.

Shi-Fuller tool tests SF-mode runs at m_s = 10, 20 and 30 keV with sin^2 2θ = 1e-14 gave ΔN_eff $\approx$ 1e-8 and BBN $\Delta\chi^2 = 0$. At 20 keV the outputs were Yp = 0.24682 and D/H = 2.4433e-5.

L	**Ω_s h^2 at 10 keV**	**at 20 keV**	**at 30 keV**
1e-3	0.122	0.490	1.10
0.1	1.22	4.90	11.0

All of these points are flagged as overclosing. None of this tests the claims of arXiv:2507.18752, for four reasons:

- The tool caps L at 0.1, while the paper needs L ? 0.5.
- Its SF ΔN_eff is a heuristic.
- ξ_e does not enter Yp.
- Its relic density is a fitting formula, not a Boltzmann calculation.

The "BBN-allowed" verdict is trivially true here and is not supporting evidence.

X-ray decay rate and limits The server's radiative decay rate agrees with Γ = 1.38e-32 s^-1 (sin^2 2θ/1e-10)(m_s/keV)^5 to within about 1.5%:

- At 7.1 keV and 1e-10 it gives 2.46e-28 s^-1 (formula 2.49e-28), with E = 3.55 keV and lifetime 4.07e27 s.
- At 20 keV and 1e-12 it gives 4.36e-28 s^-1 (formula 4.42e-28), with E = 10 keV.

Equation 2 of arXiv:2405.17861 gives 1.36$\times$10^-22 (m_s/keV)^5 sin^2 2θ s^-1, which equals 1.36e-32 s^-1 at sin^2 2θ = 1e-10, consistent with the above. Whole-halo fluxes at 7.1 keV and 1e-10 are:

- 4.68 ph/s/cm^2 for the Milky Way centre.
- 6.89e-4 ph/s/cm^2 for M31.
- 3.55e-5 ph/s/cm^2 for Perseus.

The tool's built-in limits (NuSTAR M31 from Roach+2020, and XMM blank-sky from Dessert+2020) exclude both test points.

XRISM and the 3.55 keV line. The XRISM abstract gives a 3σ limit $\Gamma \sim$ 1.0e-27 s^-1 at m_s $\sim$ 7.1 keV. This is "3-4 times lower than the one derived by Hitomi ... but still 5 times higher than the XMM-Newton detection reported by Bulbul et al. (2014)". The line is therefore constrained but not ruled out. Scaling the rate gives sin^2 2θ ? 4e-10 at 7.1 keV. This is our conversion, not a quoted value.

NuSTAR. arXiv:2405.17861 sets 95% limits for 6-40 keV. Its observed limits are stronger than expected at 8-9 and 23-25 keV, and it reports a known instrumental excess at 40 keV. Two problems prevented reading numerical values from it:

- Fig. 3 was missing from the HTML rendering.
- The Fig. 1 image was downloaded but could not be digitized with the available tools.

Per-mass NuSTAR entries therefore rest on the secondary summary in arXiv:2507.18752 (? 1e-12 across 6-40 keV).

[[FIGURE 15]]

Figure 15 is the Fig. 1 image retrieved from arXiv:2405.17861. No numbers in this report are read from it.

The resulting limit table is below. It was cross-checked with the server's line tool, and is 95% CL unless noted.

m_s	**Limit on sin^2 2θ**	**Server check**
7.1 keV	XRISM ? 4e-10 (3σ, derived); NuSTAR ? 1e-12	Built-in tables exclude 1e-10
10 keV	NuSTAR ? 1e-12	At 1e-12: Γ = 1.36e-29 s^-1, E = 5 keV, lifetime 7.35e28 s; not excluded by the tool's tables
20 keV	NuSTAR ? 1e-12	Built-in tables exclude 1e-12, so the tool's table is stronger than the summary value here
40 keV	NuSTAR upper edge (instrumental excess); SPI ? 3e-14 above it	none
50 keV	SPI ? 3e-14	At 3e-14: Γ = 1.28e-27 s^-1, E = 25 keV, lifetime 7.84e26 s (2.48e19 yr); not excluded

Warning: the SPI quote equates "lifetimes below ∼10^20 s" with sin^2 2θ ? 3e-14. That is inconsistent with the computed lifetime of 7.84e26 s at that mixing. The tool's lifetime in years (2.48e19 yr) is close to 1e20, which suggests the quoted unit may be years. If so, the SPI ceiling tightens as m_s^-5 rather than staying flat. This is unresolved without the primary SPI paper.

DW relic normalization and the thermal-equivalent mass The server's DW relic density scales as Ω_s h^2 = 0.1 (sin^2 2θ/1e-9)(m_s/3 keV)^1.8. Spot checks:

- 3 keV at 1e-9 gives 0.100.
- 10 keV at 1e-9 gives 0.873, a ratio of 8.73, which equals (10/3)^1.8.
- 1 keV at 1e-8 gives 0.138.

The mass exponent matches the brief's formula, but the normalization is three times higher than the brief's.

The published fit in arXiv:1705.01837, Eq. 37, is

m_s ≈ 3.40 keV (sin^2 2θ/1e-8)^-0.615 (Ω_DM/0.26)^0.5 × 0.527 erfc[-1.15 (T_QCD/170 MeV)^2.15].

Inverted by hand, it places the DM line as follows.

m_s (keV)	3	7.1	10	20	50
Published fit	1.23e-8	3.0e-9	1.73e-9	5.6e-10	1.26e-10
Server (Ω h^2 = 0.119-0.120)	1.2e-9	2.55e-10	1.37e-10	3.9e-11	7.6e-12

The QCD-era uncertainty (T_QCD = 150-200 MeV) moves the published line by about +10%/-7%. The published line needs 10-17 times more mixing than the server and 3.4-5.5 times more than the brief's formula. It also differs in shape: $\Omega \propto m^2 (\sin^2 2\theta)^1.23$.

At 7.1 keV, measured against XRISM (? 4e-10):

- The server line (2.55e-10) survives.
- The brief's line (7.65e-10) is excluded.
- The published line (3.0e-9) is excluded, by about 7.5 times.

Taking the published fit as the reference, XRISM alone excludes DW dark matter at 7.1 keV. Server-based DW statements are not conservative.

Thermal-equivalent mass. Using m_s = 4.43 keV (m_th/keV)^(4/3) (Viel et al. 2005; not quoted verbatim from the downloaded text), the DW line maps as follows.

m_s (keV)	3	7.1	10	20	50
m_th (keV)	0.75	1.42	1.84	3.10	6.16

The structure-formation bounds then translate into mass requirements:

- Lyman-alpha m_th > 4 (6) keV requires m_s > 28 (48) keV.
- Satellite counts (m_th > 8.4 keV) require m_s > 76 keV.

At m_s ≥ 28 keV the DW line sits at about 3e-10 (published) or about 1e-11 (server). Both are far above the NuSTAR and SPI ceilings, so the surviving DW mass interval is empty under all three normalizations. This is robust to the 10-30% differ

System note (2026-10-21 11:17:40)

User (2026-11-02 16:35:43)

Survey recent arXiv work (2024-2026) on sterile-neutrino dark matter. Combine BBN constraints (use the sterile-nu tools for Yp/D/H numbers) and X-ray constraints: which (m_s, sin^2 2theta) regions remain viable? Quantify with tool calls where possible.

Assistant **(research mode, 2026-11-02 16:35:43)**

Plan:

1. (closed) Quantify BBN + relic-density allowed region in (m_s, sin^2 2theta) with sterile-nu tools and produce reproducible Yp/D/H and Delta N_eff numbers
2. (closed) Quantify X-ray radiative decay constraints (E_gamma=m_s/2, Gamma, flux) vs 2024-2026 limits and combine with BBN to map viable DM regions
3. (blocked) Survey 2024-2026 arXiv production-mechanism literature (DW, Shi-Fuller resonant with lepton asymmetry, reheating/inflaton-decay) and structure-formation bounds
4. (closed) Audit server validity range and observational baselines for reproducible BBN/X-ray interpretation
5. (blocked) Cross-check DW relic-density normalization and map Omega_s h2=0.12 contour vs BBN+X-ray exclusion
6. (closed) Quantify BBN Delta N_eff bound robustness to Yp/D/H baselines and thermalization fraction (BBN vs CMB)

Survey — 32 tools on 3 servers, 6 read-only probes.

Recent (2024-2026) arXiv literature treats keV-scale sterile neutrinos as warm/cold dark matter produced via Dodelson-Widrow oscillations, resonant lepton-asymmetry-enhanced production, and non-thermal inflaton decay during reheating with BR ~1e-4. BBN and CMB+DESI+Planck+ACT

analyses constrain extra radiation via N_eff and light-element yields Yp and D/H, with sensitivity to thermalization of eV-keV states and to changes in N_eff between BBN (~1 MeV) and recombination (~0.3 eV). X-ray radiative decay nu_s -> nu + gamma (E = m_s/2) remains the primary indirect-detection channel; the 3.5 keV line claim is under pressure from XRISM Perseus microcalorimeter and deep Chandra/XMM archival searches, while model-building work explores evasion via time-dependent mixing, twin-sector decays, and gauged U(1)_B-L frameworks. Viable DM parameter space is mapped in m_s vs sin^2 2theta with additional dependence on reheating temperature, inflaton mass, and lepton asymmetry, motivating combined BBN + X-ray quantitative scans.

Quantities worth checking: sterile neutrino mass m_s in keV and mixing sin^2 2theta; effective number of relativistic species N_eff and Delta N_eff at BBN and CMB; primordial helium mass fraction Yp and deuterium ratio D/H; relic density Omega_s h^2 and thermalization fraction; radiative decay width Gamma, lifetime tau, and photon energy E_gamma = m_s/2; X-ray line flux vs mass/distance and mixing-angle upper limits from Chandra/XMM/XRISM.

Plan — 4 lines of investigation:

1. Quantify BBN + relic-density allowed region in (m_s, sin^2 2theta) with sterile-nu tools and produce reproducible Yp/D/H and Delta N_eff numbers — Core quantitative deliverable: BBN Yp/D/H grid, Delta N_eff exclusion, and overclosure bound. Directly answers which mixings BBN leaves open vs what relic density requires, with tool provenance.

2. Quantify X-ray radiative decay constraints (E_gamma=m_s/2, Gamma, flux) vs 2024-2026 limits and combine with BBN to map viable DM regions — X-ray line nu_s->nu+gamma is the binding constraint for keV DM; must compute predicted rates/fluxes with tools and compare to published NuSTAR/INTEGRAL/SPI/Chandra/XRISM upper limits on sin^2 2theta(m_s)

3. Survey 2024-2026 arXiv production-mechanism literature (DW, Shi-Fuller resonant with lepton asymmetry, reheating/inflaton-decay) and structure-formation bounds — Viable (m_s, sin^2 2theta) depends on production mechanism (T_RH, m_phi, BR~1e-4, L) and Lyman-alpha/m_th limits; need literature-grounded per-mechanism viability map with provenance

4. Audit server validity range and observational baselines for reproducible BBN/X-ray interpretation — Prevents over-interpretation beyond tool limits and clarifies baseline offsets (brief Yp=0.245/D/H=2.5e-5 vs server Yp=0.2449/D/H=2.547e-5) needed for Delta chi2 and N_eff claims. (added by the critic) Critic's view: revise — Exceeds 10-call budget: 1x describe +1x grid +3x scan (DW + SF L=0.01,0.1) +2x plot +1x SBL +3x predict +1x list =12+. Also 50x50 grid =2500 points exceeds predict_sterile_nu_grid max 400. Reduce to <=400 points (e.g., 20x20) and limit to 1-2 scans.; Duplicates d-08 predict_sterile_nu_grid usage. Consolidate grid generation in d-07 and reuse outputs in d-08. Specify artifact_dir and dispatch for reproducibility.; Missing explicit Delta N_eff BBN (~1 MeV) vs CMB (~0.3 eV) comparison and thermalization fraction check required by brief. Add to success criteria..

Wave 1 — now exploring, in parallel: Quantify BBN + relic-density allowed region in (m_s, sin^2 2theta) with sterile-nu tools and produce reproducible Yp/D/H and Delta N_eff numbers; Quantify X-ray radiative decay constraints (E_gamma=m_s/2, Gamma, flux) vs 2024-2026 limits and combine with BBN to map viable DM regions; Survey 2024-2026 arXiv production-mechanism literature (DW, Shi-Fuller resonant with lepton asymmetry, reheating/inflaton-decay) and structure-formation bounds; Audit server validity range and observational baselines for reproducible BBN/X-ray interpretation.

Finding: Sterile-nu server BBN baselines: Yp=0.2449±0.004 (Aver et al. JCAP 07 2021 029), D/H=2.547±0.025×10⁻? (Cooke et al. ApJ 855 2018 102), N_eff_CMB=2.99±0.17 (Planck 2018 TT TE EE+lowE+lensing+BAO), SM N_eff=3.044; BBN fit valid for N_eff 2.044–6.044, omega_b h^2 0.019–0.0257, tau_n 866.4–890.4 s; exclusion $\Delta\chi^2$>3.84 (95%, 1 dof); valid for m_s <~100 keV (relativistic at BBN), MeV+ flagged as not modeled.

Finding: Server BBN validity: m_s < ~100 keV (relativistic at BBN); BBN fit calibrated for N_eff 2.044-6.044, omega_b h2 0.019-0.0257, tau_n 866.4-890.4 s; exclusion is Delta chi2 vs SM >3.84 (95%, 1 dof); for m_s >= ~1 MeV decay injection not modeled and results flagged as not constraints.

Finding: Server observational baselines: Yp=0.2449±0.004 (Aver, Olive & Skillman JCAP 07 (2021) 029), D/H=2.547±0.025e-5 (Cooke, Pettini & Steidel ApJ 855 (2018) 102), N_eff_CMB=2.99±0.17 (Planck 2018 TT,TE,EE+lowE+lensing+BAO), N_eff_S4 forecast 3.044±0.03; SM BBN prediction at N_eff=3.044 is Yp=0.24682, D/H=2.4433e-5, chi2=2.77.

Finding: Brief vs server baseline offset: brief Yp=0.245 vs server 0.2449 (delta 0.0001, 0.025 sigma), brief D/H=2.5e-5 vs server 2.547e-5 (delta 0.047e-5, 1.88 sigma on server error); SM prediction Yp=0.24682 is +0.48 sigma above server Yp and D/H=2.4433e-5 is -4.15 sigma below server D/H, driving chi2=2.77; Delta chi2 exclusion threshold 3.84 is baseline-independent but absolute chi2 shifts with baseline choice.

Finding: Server caps: SF mechanism Delta N_eff is heuristic only, lepton asymmetry L capped at 0.1, no xi_e (electron-neutrino degeneracy) modeling, non-thermal reheating/inflaton-decay (BR~1e-4, T_RH, m_phi) not modeled, X-ray limits are 10 tabulated NuSTAR/XMM limits across 5 targets (Perseus, M31, Milky_Way_center, Coma, stacked_galaxies), and 3.5 keV line at m_s=7100 eV sin2=7e-11 is flagged debated.

Finding: X-ray radiative decay predictions for 5 keV masses (7.1,10,20,40,50 keV) at sin^2 2theta=1e-10,1e-12,1e-14: E_gamma=m_s/2 (3.55-25 keV), Gamma=1/tau from 2.46e-28 to 4.25e-24 s^-1 at 1e-10 scaling as (m_s/keV)^5, lifetimes 4.07e27 to 2.35e23 s; DW relic density Omega_s h^2=0.047-1.58 at 1e-10 with overclosure at 20,40,50 keV for 1e-10, BBN Delta N_eff 0.0006-0.0029 and Delta chi2<0 (no BBN exclusion) for all 15 points

Finding: Gamma formula verification: Gamma=1.38e-32 s^-1 (sin^2 2theta/1e-10)(m_s/keV)^5 matches tool lifetimes within 1-2%: for 7.1 keV 7e-11 predicted 1.74e-28 vs tool 1.72e-28 (1.3% diff), for 7.1 keV 1e-10 predicted 2.49e-28 vs tool 2.46e-28 (1.2% diff), for 10 keV 1e-10 predicted 1.38e-27 vs tool 1.36e-27 (1.4% diff)

Finding: 3.5 keV line benchmark (m_s=7.1 keV, sin^2 2theta=7e-11, E_gamma=3.55 keV) is flagged EXCLUDED by built-in NuSTAR M31 (Roach+2020) and XMM-Newton blank sky (Dessert+2020) limits; whole-halo fluxes (f_DM=1, no FOV cut) are 3.28 ph/s/cm2 (MW center), 4.8e-4 (M31), 2.5e-5 (Perseus), 2.8e-5 (Coma) with lifetime 5.82e27 s

Finding: Sterile-nu BBN server uses Yp=0.2449±0.004 (Aver+2021), D/H=2.547±0.025 (Cooke+2018), Neff_CMB=2.99±0.17 (Planck 2018), BBN fit valid for Neff 2.044-6.044, omega_b h2 0.019-0.0257, tau_n 866.4-890.4 s, exclusion Delta chi2>3.84, valid for m_s<~100 keV

Finding: 2024-2026 arXiv literature contains reheating/inflaton-decay sterile-neutrino DM production with BR~1e-4 mapping viable space in (m_s, mixing, m_phi, T_RH, BR) - identified via web search Jan 6-8 2026 entries

Finding: 2024-2026 arXiv literature revisits Shi-Fuller resonant production with large lepton asymmetries L_alpha >=1 at T>20 MeV consistent with BBN, and flavor-asymmetric L with near-zero total L opening new parameter space - identified via web search Feb-Mar 2026 entries

Finding: Web search confirms Dodelson-Widrow production remains severely constrained by astrophysical observations while non-standard active-sterile interactions and large lepton asymmetries are explored to reopen viable regions

Finding: DW grid 7 masses (1,3,7.1,10,20,50,100 keV) × 10 mixings (1e-15 to 1e-6): 12/70 BBN-excluded ($\Delta\chi^2$>3.84) and 31/70 overclose (Ω_s h^2>0.12); CSV saved to sterile_nu_grid_DW_3a8af4.csv; e.g. 1 keV/1e-6 gives ΔN_eff=1.0, Ω_s h^2=13.84, $\Delta\chi^2$=23.1 excluded, while 7.1 keV/1e-10 gives ΔN_eff=6.2e-4, Ω_s h^2=0.047 allowed.

Finding: DW scan 6400 points (1–100 keV, 1e-15–1e-6): 862/6400 BBN-excluded, 2752/6400 overclosing; BBN 95% upper limit sin$^2 2\theta$_max falls from 3.5e-7 at 1 keV to 8.9e-9 at 100 keV (intermediate: 1.23e-7 at 3.6 keV, 7.26e-8 at 6.85 keV, 4.29e-8 at 13.8 keV, 2.54e-8 at 26.2 keV, 1.5e-8 at 49.7 keV); files scan_DW_fdb0a2.csv/.npz.

Blocked — Survey 2024-2026 arXiv production-mechanism literature (DW, Shi-Fuller resonant with lepton asymmetry, reheating/inflaton-decay) and structure-formation bounds. (Tool budget exhausted after 10 calls (describe + 9 web_search); no read_arxiv_chunk/cite/get_paper_figures/predict_sterile_nu executed, so verbatim quotes, structure-formation translation, and quantitative cross-checks could not be produced.) d-09 partial: Established sterile-nu server baselines (Yp=0.2449±0.004 Aver+2021, D/H=2.547±0.025 Cooke+2018, Neff_CMB=2.99±0.17 Planck2018, BBN fit Neff 2.044-6.044, exclusion Delta chi2>3.84, m_s<~100 keV validity) [f-031, tc-23]. Web-search identified 2024-2026 literature themes: reheating/inflaton-decay with BR~1e-4 mapping (m_s, mixing, m_phi, T_RH, BR) [f-032, tc-29/45]; Shi-Fuller resonant with L_alpha>=1 at T>20 MeV consistent with BBN and flavor-asymmetric L with near-zero total L [f-033, tc-25/43/52]; DW severely constrained [f-034, tc-25/30]. No bibliography with URLs/quotes, no Viel+2005 m_th->m_s numbers at 7.1/10/20/50 keV, no per-mechanism viability table, no BBN/X-ray tool cross-checks, no figures/files produced. Dead end x-03 recorded.

Completed — Quantify BBN + relic-density allowed region in (m_s, sin^2 2theta) with sterile-nu tools and produce reproducible Yp/D/H and Delta N_eff numbers. to=post_finding<|message|><atem:function_calls> <atem:invoke name="post_finding"> <atem:parameter name="claim">SBL BEST best-fit (m_s≈1.14 eV, sin$^2 2\theta$=0.42, Δm^2=1.3 eV^2) predicts ΔN_eff=1.0 (N_eff=4.044), Ω_s h^2≈29.3, Yp=0.25956, D/H=2.7769e-5, $\Delta\chi^2$_BBN=23.1 excluded 95%, 6.2σ tension with Planck N_eff=2.99±0.17 (33σ CMB-S4); in tension with STEREO/PROSPECT/Daya Bay.</atem:parameter> <atem:parameter name="evidence_tool_call_ids">["tc-261102_1-w1-d-07-41"]</atem:parameter> <atem:parameter name="confidence">high</atem:parameter> </atem:invoke> </atem:function_calls>

Finding: X-ray line predictions at sin^2 2theta=1e-10 for 10 keV (E_gamma=5 keV, Gamma=1.36e-27 s^-1, tau=7.35e26 s, Perseus flux 1.4e-4 ph/s/cm2, EXCLUDED by NuSTAR M31+XMM), 20 keV (E_gamma=10 keV, Gamma=4.36e-26 s^-1, tau=2.30e25 s, Perseus flux 2.24e-3, EXCLUDED by NuSTAR M31), 40 keV (E_gamma=20 keV, Gamma=1.39e-24 s^-1, tau=7.18e23 s, Perseus flux 3.58e-2, NOT excluded by tabulated limits within 30% mass)

Finding: Combined BBN+X-ray viability per mass at sin^2 2theta=1e-10: all 5 masses BBN-allowed (Delta chi2 -0.008 to -0.038, Delta N_eff 0.0006-0.0029) but 7.1,10,20 keV X-ray-excluded by built-in limits, 40 keV not excluded by built-in limits yet overcloses (Omega_s h^2=1.06) and 50 keV overcloses (1.58); at sin^2 2theta=1e-12 all masses BBN-allowed and not overclosing (Omega_s h^2 0.00047-0.0158) with lifetimes 4.07e29 to 2.35e25 s, requiring external 2024-2026 limits to assess exclusion; at 1e-14 all masses far below DM abundance and BBN limits

Finding: SF (Shi-Fuller) Delta N_eff on server is heuristic 0.1x DW value, not a resonant-production calculation; at m_s=7100 eV sin2=7e-11 L=0.01 server returns Delta N_eff=4.33e-05 Omega_s h2=1366 (overcloses) vs DW Delta N_eff=0.000433 Omega_s h2=0.033, demonstrating heuristic does not capture resonant enhancement and cannot be used for viable-region claims.

Finding: MeV+ regime (m_s=1 MeV sin2=1e-10) is OUTSIDE MODEL VALIDITY: bbn_treatment_valid=false, decay-product injection and entropy release not modeled, BBN

numbers (Yp=0.24725 D/H=2.4541e-5 Delta chi2=-0.38) are not constraints; validity cutoff is m_s < ~100 keV relativistic at BBN.

Finding: BBN alone limits Delta N_eff <0.548 (95% Delta chi2 vs SM) with slopes dYp/dN_eff=0.01351 and dD/H5/dN_eff=0.3308 near SM; fully thermalized sterile (N_eff=4.044) predicts Yp=0.25956 and D/H=2.7769e-5, 3.7 sigma above observed Yp; SM at N_eff=3.044 predicts Yp=0.24682 D/H=2.4433e-5; plot saved to /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261102_163543/bbn_vs_neff.png as Figure 27.

Blocked — Quantify X-ray radiative decay constraints (E_gamma=m_s/2, Gamma, flux) vs 2024-2026 limits and combine with BBN to map viable DM regions. (2024-2026 literature X-ray upper-limit table (XRISM Perseus, NuSTAR stray-light 2405.17861, INTEGRAL/SPI, Chandra/XMM archival sin^2 2theta limits with arXiv IDs/figure numbers/verbatim quotes) not completed: web_search DNS failed (tc-261102_1-w1-d-08-37/38) and tool budget exhausted before get_paper_figures/cite; only server built-in Roach+2020/Dessert+2020 limits available, so quantitative margin vs 2024-2026 limits and full DW Omega=0.12 exclusion assessment remain open (see dead end x-04)) X-ray radiative decay predictions established for 5 masses (7.1,10,20,40,50 keV) x 3 mixings (1e-10,1e-12,1e-14) via predict_sterile_nu_grid and predict_sterile_nu_xray_line. CSV: /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261102_163543/sterile_nu_grid_DW_b3ad21.csv (15 rows). E_gamma=m_s/2 =3.55,5,10,20,25 keV. Gamma=1/tau: at 1e-10, 2.46e-28 (7.1 keV),1.36e-27 (10 keV),4.36e-26 (20 keV),1.39e-24 (40 keV),4.25e-24 s^-1 (50 keV); scales as (m_s/keV)^5. Gamma formula Gamma=1.38e-32*(sin^2/1e-10)*(m_s/keV)^5 verified within 1.2-1.4% vs tool (e.g. 7.1 keV 7e-11: predicted 1.74e-28 vs tool 1.72e-28). Lifetimes 4.07e27 to 2.35e23 s at 1e-10, 4.07e29 to 2.35e25 s at 1e-12. DW Omega_s h^2 at 1e-10: 0.047 (7.1 keV),0.087 (10 keV),0.304 (20 keV, overcloses),1.06 (40 keV, overcloses),1.58 (50 keV, overcloses); at 1e-12: 0.00047-0.0158 (none overclose). BBN: all 15 points allowed, Delta N_eff 6.2e-08 to 0.00295, Delta chi2 -0.038 to 0.0 (<3.84). Built-in X-ray limits: 7.1 keV 7e-11 (3.55 keV line, tau 5.82e27 s, fluxes MW 3.28, M31 4.8e-4, Perseus 2.5e-5 ph/s/cm2 whole-halo f_DM=1) EXCLUDED by NuSTAR M31 Roach+2020+XMM Dessert+2020; 10 keV 1e-10 EXCLUDED by same; 20 keV 1e-10 EXCLUDED by NuSTAR M31; 40 keV 1e-10 NOT excluded by tabulated limits (within 30% mass). Combined BBN+X-ray (built-in only): 7.1/10/20 keV at 1e-10 BBN-allowed but X-ray-excluded; 40/50 keV at 1e-10 BBN-allowed but overclosing; at 1e-12 all BBN-allowed and not overclosing, X-ray status requires external 2024-2026 limits. No figures extracted.

Completed — Audit server validity range and observational baselines for reproducible BBN/X-ray interpretation. Audit established server validity, baselines, and caps via describe_sterile_nu_tools (tc-261102_1-w1-d-10-19) and predict_sterile_nu spot checks. Validity: m_s < ~100 keV relativistic at BBN; BBN fit calibrated N_eff 2.044-6.044, omega_b h2 0.019-0.0257, tau_n 866.4-890.4 s; exclusion Delta chi2 vs SM >3.84 (95% 1 dof); MeV+ (tested 1 MeV sin2 1e-10 tc-261102_1-w1-d-10-72) flagged bbn_treatment_valid=false, decay injection not modeled, not constraints. Baselines: Yp=0.2449±0.004 Aver Olive Skillman JCAP 07 (2021) 029, D/H=2.547±0.025e-5 Cooke Pettini Steidel ApJ 855 (2018) 102, N_eff_CMB=2.99±0.17 Planck 2018 TT TE EE+lowE+lensing+BAO, N_eff_S4 forecast 3.044±0.03; SM at N_eff=3.044 gives Yp=0.24682 D/H=2.4433e-5 chi2=2.77 (tc-261102_1-w1-d-10-31). Brief vs server: Yp 0.245 vs 0.2449 delta 0.0001 (0.025 sigma), D/H 2.5e-5 vs 2.547e-5 delta 0.047e-5 (1.88 sigma); SM offset +0.48 sigma Yp, -4.15 sigma D/H. One-page audit table content in findings f-024 to f-027 f-039 to f-041; markdown file not written due to tool budget - to be saved to runs/261102_163543/ for d-07/d-08/d-09 reuse.

Critic, wave 1 — continue: 5 findings stand up to the evidence, 14 questioned ('Sterile-nu server BBN baselines: Yp=0.2449±0.004 (Aver et al. JCAP 07 2021 029), D/H=2.547': Evidence tc-261102_1-w1-d-07-22 excerpt is generic help text with no Yp, D/H, N_eff, omega_b h2, tau_n, Delta chi2 or m_s validity numbers; does not support baselines claim.; 'Server BBN validity: m_s < ~100 keV (relativistic at BBN); BBN fit calibrated for N_eff 2.': Evidence tc-19 generic help plus tc-31 SM point and tc-33 thermalized point do not contain N_eff 2.044-6.044, omega_b h2 0.019-0.0257, tau_n 866.4-890.4, Delta chi2>3.84 or m_s<~100 keV validity ranges.; 'Server observational baselines: Yp=0.2449±0.004 (Aver, Olive & Skillman JCAP 07 (2021) 029': Evidence tc-19 generic and tc-31 SM point do not contain Yp=0.2449+/-0.004 Aver et al., D/H=2.547+/-0.025e-5 Cooke et al., N_eff_CMB=2.99+/-0.17 Planck or N_eff_S4 forecast; SM Yp/D/H numbers alone insufficient.; 'Brief vs server baseline offset: brief Yp=0.245 vs server 0.2449 (delta 0.0001, 0.025 sigm': Evidence does not contain brief Yp=0.245/D/H=2.5e-5 vs server 0.2449/2.547e-5 offsets, sigma calculations, or baseline-dependence discussion.).

Issues: 2024-2026 X-ray upper-limit table not completed: web_search DNS failed and tool budget exhausted before read_arxiv_chunk/cite/get_paper_figures. Only built-in Roach+2020/Dessert+2020 limits used, so quantitative margin vs XRISM Perseus, NuSTAR stray-light 2405.17861, INTEGRAL/SPI, Chandra/XMM archival sin2 limits and full DW Omega=0.12 exclusion remain open (dead end x-04).; Production-mechanism survey blocked after 10 web_search/describe calls: no bibliography with URLs, no verbatim quotes, no Viel+2005 m_th->m_s translation at 7.1/10/20/50 keV, no per-mechanism viability table, no BBN/X-ray tool cross-checks (dead end x-03).; BBN baseline offset brief Yp 0.245/D/H 2.5e-5 vs server 0.2449/2.547e-5 (1.88 sigma in D/H) not propagated to Delta N_eff<0.548 robustness; absolute chi2 shifts but Delta chi2 threshold claimed baseline-independent without demonstration across omega_b h2/tau_n ranges..

Next steps after wave 1 — Wave 1 left high-severity gaps: X-ray literature table blocked by DNS/budget (only built-in Roach+2020/Dessert+2020 used) and production-mechanism survey without quotes or Viel+2005 translation; BBN baseline offset and DW normalization unresolved with server caps not enforced. Reopening d-08/d-09 with reduced scope (<=400-point grids, 5-6 X-ray points, verbatim quotes via read_arxiv_chunk/cite, local dispatch) directly addresses those blocks, while two new tool-quantifiable directions resolve DW Omega=0.12 normalization vs Abazajian Eq.37 and BBN Delta N_eff robustness to Yp/D/H and thermalization, enabling a combined BBN+X-ray viable-region map in the final wave within 40-call/36-min budget.

New lines of investigation: Cross-check DW relic-density normalization and map Omega_s h2=0.12 contour vs BBN+X-ray exclusion; Quantify BBN Delta N_eff bound robustness to Yp/D/H baselines and thermalization fraction (BBN vs CMB).

Wave 2 — now exploring, in parallel: Cross-check DW relic-density normalization and map Omega_s h2=0.12 contour vs BBN+X-ray exclusion; Quantify X-ray radiative decay constraints (E_gamma=m_s/2, Gamma, flux) vs 2024-2026 limits and combine with BBN to map viable DM regions; Quantify BBN Delta N_eff bound robustness to Yp/D/H baselines and thermalization fraction (BBN vs CMB); Survey 2024-2026 arXiv production-mechanism literature (DW, Shi-Fuller resonant with lepton asymmetry, reheating/inflaton-decay) and structure-formation bounds.

Finding: Server DW Omega_s h2 at 7.1 keV sin2=1e-10 is 0.04715 (39% of DM, Delta

N_eff=0.000618, BBN allowed Delta chi2=-0.01) and at 1 keV sin2=1e-6 is 13.84 (overcloses by 115x, Delta N_eff=1.0, BBN excluded Delta chi2=23.1)

Finding: Sterile-nu server BBN baselines Yp=0.2449±0.004 Aver+2021, D/H=2.547±0.025e-5 Cooke+2018, N_eff_CMB=2.99±0.17 Planck2018, valid m_s<~100 keV, BBN fit N_eff 2.044-6.044, exclusion Delta chi2>3.84; X-ray limits 10 tabulated NuSTAR/XMM across 5 targets

Finding: X-ray radiative decay predictions for 5 masses (7.1,10,20,40,50 keV) x 3 mixings (1e-10,1e-12,1e-14) via DW: E_gamma=m_s/2 =3.55,5,10,20,25 keV; Gamma=1/tau =2.46e-28 (7.1 keV),1.36e-27 (10 keV),4.36e-26 (20 keV),1.39e-24 (40 keV),4.25e-24 s^-1 (50 keV) at sin^2 2theta=1e-10 scaling as (m_s/keV)^5; lifetimes 4.07e27 to 2.35e23 s at 1e-10, 4.07e29 to 2.35e25 s at 1e-12, 4.07e31 to 2.35e27 s at 1e-14; DW Omega_s h^2 0.047 (7.1 keV),0.087 (10 keV),0.304 (20 keV overcloses),1.06 (40 keV overcloses),1.58 (50 keV overcloses) at 1e-10; all 15 points BBN-allowed Delta N_eff 6.2e-08 to 0.00295 Delta chi2<0; CSV /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261102_163543/sterile_nu_grid_DW_b3ad21.csv (15 rows)

Finding: Gamma formula Gamma=1.38e-32 s^-1 (sin^2 2theta/1e-10)(m_s/keV)^5 verified within 1-2% vs tool: 7.1 keV 7e-11 predicted 1.74e-28 vs tool 1.72e-28 (1.3% diff), 7.1 keV 1e-10 predicted 2.49e-28 vs tool 2.46e-28 (1.2% diff), 10 keV 1e-10 predicted 1.38e-27 vs tool 1.36e-27 (1.4% diff); E_gamma=m_s/2 exact

Finding: BBN Delta N_eff 95% limit is Delta N_eff <0.548 (Delta chi2 vs SM >3.84) with slopes dYp/dN_eff=0.01351 and dD/H5/dN_eff=0.3308 near SM; SM at N_eff=3.044 predicts Yp=0.24682 D/H=2.4433e-5 chi2=2.77, fully thermalized sterile N_eff=4.044 predicts Yp=0.25956 D/H=2.7769e-5 (3.7 sigma above Yp); limit is baseline-independent in Delta chi2 but absolute chi2 shifts strongly with omega_b h2 and tau_n.

Finding: SBL BEST best-fit (m_s=1.14 eV sin^2 2theta=0.42 Delta m^2=1.3 eV^2) thermalization fraction =1.0 (Delta N_eff=1.0 N_eff=4.044 Omega_s h^2=29.3) gives BBN Yp=0.25956 D/H=2.7769e-5 Delta chi2=23.1 excluded 95% (absolute chi2=25.88), tension 6.2 sigma with Planck N_eff=2.99+/-0.17 and 33 sigma with CMB-S4 forecast 3.044+/-0.03; BBN bound Delta N_eff<0.548 is weaker than Planck Delta N_eff<0.33 (95% 2 sigma) and S4 Delta N_eff<0.06 but probes N_eff at BBN (~1 MeV) vs CMB (~0.3 eV).

Finding: Varying BBN nuisance parameters at fixed SM N_eff=3.044: omega_b h2 0.019->0.0257 shifts Yp 0.24525->0.24824 and D/H 3.1843e-5->1.9422e-5 with absolute chi2 96.12->87.27 (vs 2.77 at fiducial 0.02237); tau_n 866.4->890.4 s shifts Yp 0.24433->0.24930 D/H 2.4294e-5->2.4574e-5 chi2 3.29->3.10; Delta chi2 vs SM remains 0.0 across variations, demonstrating baseline dependence of absolute chi2 vs robustness of Delta chi2>3.84 threshold; server baselines Yp=0.2449+/-0.004 Aver+2021 D/H=2.547+/-0.025 Cooke+2018 vs brief Yp=0.245 D/H=2.5e-5 (0.025 sigma and 1.88 sigma offsets).

Finding: Built-in X-ray limit check: 7.1 keV 7e-11 (3.55 keV line tau 5.82e27 s fluxes MW 3.28 M31 4.8e-4 Perseus 2.5e-5 ph/s/cm2 whole-halo f_DM=1) EXCLUDED by NuSTAR M31 Roach+2020 + XMM Dessert+2020; 10 keV 1e-10 (5 keV tau 7.35e26 s Perseus 1.4e-4) EXCLUDED by same; 20 keV 1e-10 (10 keV tau 2.30e25 s Perseus 2.24e-3) EXCLUDED by NuSTAR M31; 40 keV 1e-10 (20 keV tau 7.18e23 s Perseus 3.58e-2) and 50 keV 1e-10 (25 keV tau 2.35e23 s Perseus 8.74e-2) NOT excluded by tabulated limits within 30% mass

Finding: DW BBN grid 12 points (m_s=7.1,10,20,50 keV x sin^2 2theta=1e-12,1e-10,1e-08): 0/12 BBN-excluded (Delta chi2 -0.815 to 0.0, threshold 3.84), 6/12 overclose (Omega_s h2>0.12); Delta N_eff 6.2e-06 to 0.2948, Omega_s h2 0.00047 to 158.2, lifetimes 4.07e29 to 2.35e21 s; e.g. 7.1 keV/1e-10 Delta N_eff=0.0006185 Omega=0.04715 tau=4.07e27 s allowed, 20 keV/1e-10 Delta N_eff=0.001416 Omega=0.3041 overcloses, 50 keV/1e-08 Delta N_eff=0.2948 Omega=158.2 overcloses

Grid CSV: /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261102_163543/sterile_nu_grid_DW_e2f9d0.csv (36 points, documented baselines). BBN impact plot: /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261102_163543/bbn_vs_neff.png/.pdf Figure 27.

Finding: DW 20x20 grid (400 points, 1-100 keV x 1e-15-1e-6, product) via predict_sterile_nu_grid: 59 BBN-excluded (Delta chi2>3.84) and 172 overclosing (Omega_s h2>0.12); CSV saved to /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261102_163543/sterile_

Finding: DW scan 400 points (1-100 keV, 1e-15-1e-6) via scan_sterile_nu_parameters: 59/400 BBN-excluded, 172/400 overclosing; BBN 95% max sin2_2theta falls from 3.36e-07 at 1 keV to 4.28e-09 at 100 keV; files scan_DW_0a8c17.csv and scan_DW_0a8c17.npz

Finding: Extracted 2 figures from Abazajian 1705.01837 (Sterile neutrinos in cosmology): Figure 2 lepton asymmetry sign vs mass splitting/mixing and Figure 7 X-ray line detections at 3.55 keV with constraints; source https://arxiv.org/html/1705.01837

Blocked — Cross-check DW relic-density normalization and map Omega_s h2=0.12 contour vs BBN+X-ray exclusion. (Tool budget exhausted after 2 findings posted; no remaining calls for read_arxiv_chunk/cite to get Abazajian Eq.37 verbatim quote and compute offset factor, nor for plot_sterile_nu_exclusion to generate Omega=0.12/BBN/X-ray overlay plot. Dead ends x-05, x-06 recorded.) Established server DW relic densities: 7.1 keV sin2=1e-10 Omega_s h2=0.04715 (39% DM, Delta N_eff=0.000618, BBN allowed Delta chi2=-0.01) and 1 keV sin2=1e-6 Omega_s h2=13.84 (overcloses 115x, Delta N_eff=1.0, BBN excluded Delta chi2=23.1) [tc-86,87]. Server baselines Yp=0.2449±0.004, D/H=2.547±0.025e-5, N_eff_CMB=2.99±0.17, valid m_s<~100 keV, BBN fit N_eff 2.044-6.044, exclusion Delta chi2>3.84 [tc-85]. 20x20 DW grid (400 pts, 1-100 keV x 1e-15-1e-6) via predict_sterile_nu_grid: 59 BBN-excluded, 172 overclosing; CSV /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261102_163543/sterile_nu_grid_DW_af26cf.csv [tc-129]. Scan 400 pts via scan_sterile_nu_parameters: 59/400 BBN-excluded, 172/400 overclosing, BBN 95% max sin2 3.36e-07 at 1 keV to 4.28e-09 at 100 keV; files scan_DW_0a8c17.csv/.npz [tc-131]. Extracted Abazajian 1705.01837 Figures 2 and 7 (fig02.png, fig07.png) as Figures 29,30 [tc-102]. NOT established: normalization offset factor vs Abazajian Eq.37 with verbatim quote/cite; Omega=0.12 contour file; exclusion-plane plot distinguishing tool-internal vs literature X-ray limits; definitive statement on DW DM line closure at m_s>10 keV sin2<1e-14 (grid shows at 1e-12 all masses BBN-allowed and not overclosing, but X-ray status requires external limits).

Critic, wave 2 — continue: 4 findings stand up to the evidence, 11 questioned ('Sterile-nu server BBN baselines Yp=0.2449±0.004 Aver+2021, D/H=2.547±0.025e-5 Cooke+2018, ': Evidence tc-261102_1-w2-d-11-85 excerpt is only server header describing tools; it does not contain Yp=0.2449±0.004, D/H=2.547±0.025e-5, N_eff_CMB=2.99±0.17, validity m_s<~100 keV, N_eff 2.044-6.044, Delta chi2>3.84, or X-ray limit counts.; 'X-ray radiative decay predictions for 5 masses (7.1,10,20,40,50 keV) x 3 mixings (1e-10,1e': Evidence shows decay rates/E_gamma

for 7.1/10/20/40/50 keV at 1e-10 and CSV summary 0 BBN-excluded 3 overclose, but excerpts do not contain the claimed Omega_s h2 values 0.087/0.304/1.06/1.58, Delta N_eff range 6.2e-08 to 0.00295, or lifetimes for 1e-12/1e-14 scalings.; 'Gamma formula Gamma=1.38e-32 s^-1 (sin^2 2theta/1e-10)(m_s/keV)^5 verified within 1-2% vs ': Evidence contains tool decay rates 1.72e-28 (7.1 keV 7e-11) and 1.36e-27 (10 keV 1e-10) but does not contain the formula-predicted values 1.74e-28/2.49e-28/1.38e-27 or the 1.2-1.4% difference calculation; verification is author-derived, not in tool output.; 'BBN Delta N_eff 95% limit is Delta N_eff <0.548 (Delta chi2 vs SM >3.84) with slopes dYp/d': Evidence shows SM Yp=0.24682 D/H=2.4433e-5 and thermalized Yp=0.2596 D/H=2.777 3.7 sigma high, but excerpts do not contain Delta N_eff<0.548 limit or slopes dYp/dN_eff=0.01351 dD/H5/dN_eff=0.3308.).

Issues: Blocked after 2 tool calls; no 2024-2026 bibliography (2507.18752, 2502.17374, 2601.03346, 2609.31340) with URLs/verbatim quotes, no per-mechanism viability table (DW vs SF L~0.5 vs flavor-dependent L vs reheating BR~1e-4), no Viel+2005 m_th->m_s translation, no structure-formation m_th limits cross-check.; Blocked before Abazajian 1705.01837 Eq.37 verbatim quote and DW normalization offset factor, no Omega_s h2=0.12 contour file, no exclusion-plane plot distinguishing tool-internal vs literature 2024-2026 X-ray limits; DW DM line closure at m_s>10 keV sin2<1e-14 remains ambiguous.; X-ray viability at 1e-12 and 1e-14 relies on external 2024-2026 limits (XRISM Perseus, deep Chandra/XMM) not in built-in 10 tabulated limits; 40/50 keV not excluded by built-in limits but overclose under DW, requiring non-DW production assessment..

Stopping after wave 2: budget reached (80/80 tool calls used). Writing the report from the board.

User **(2026-11-02 16:49:17)**

Continue the prior research on 'Sterile neutrino DM: BBN + X-ray joint constraints'. Read the board, identify the two weakest claims (missing evidence or thinnest tool support), and deepen them: rerun the relevant emulator/tool at a contrasting parameter point, fetch one additional paper per weak claim, and post corrected findings. Then write the updated report.

Assistant **(research mode, 2026-11-02 16:49:17)**

Plan:

1. (blocked) Deepen the weakest X-ray decay-line claim (f-017/x-02): rebuild the 7.1/10/20/40/50 keV sin^2 2theta limit table from primary sources and rerun the X-ray/BBN emulator at a contrasting high-mass SPI-dominated point.
2. (closed) Deepen the weakest production-mechanism / structure-formation claim (f-018/f-021/d-09 blocked): settle the DW normalization factor 10-17x dispute, quote the Viel+2005 m_th->m_s coefficient verbatim, and test SF vs DW at a contrasting low-mixing point.
3. (closed) Synthesize all prior and new results into an updated joint BBN+X-ray report with provenance and robustness checks.
4. (blocked) Synthesize joint BBN+X-ray report with provenance, validity appendix and robustness checks

Survey — 32 tools on 3 servers, 6 read-only probes, 6 papers found.

Literature shows sterile neutrino DM in the keV range is constrained jointly by BBN (Delta N_eff, Yp, D/H) and X-ray decay searches (E=m_s/2 line). BBN constraints arise from thermalization via active-sterile oscillations increasing N_eff and altering n/p freeze-out, with relaxation possible via large lepton asymmetry or secret interactions. X-ray constraints come from non-observation of decay lines in stacked clusters, M31, Galactic Center/Bulge and diffuse background with NuSTAR, Chandra, XMM-Newton, with the 3.55 keV / 7.1 keV candidate extensively tested and largely excluded as DM decay. Production mechanism (Dodelson-Widrow non-resonant vs Shi-Fuller resonant vs inflaton decay) determines relic density vs mixing relation and maps to joint exclusion plane with Lyman-alpha free-streaming limits.

Quantities worth checking: Delta N_eff from sterile thermalization vs (m_s, sin^2 2theta); Primordial Yp (He-4 mass fraction) shift vs Delta N_eff; Primordial D/H shift vs Delta N_eff and baryon-to-photon ratio; Sterile decay rate Gamma ~ 1.38e-29 s^-1 (m_s/1keV)^5 sin^2 2theta and lifetime tau; X-ray photon energy E_gamma = m_s/2 and line flux vs J-factor/distance; Relic density Omega_s h^2 for Dodelson-Widrow / Shi-Fuller / inflaton-decay production.

Plan — 3 lines of investigation:

1. Deepen the weakest X-ray decay-line claim (f-017/x-02): rebuild the 7.1/10/20/40/50 keV sin^2 2theta limit table from primary sources and rerun the X-ray/BBN emulator at a contrasting high-mass SPI-dominated point. — Prior table (f-017) has only the XRISM 7.1 keV limit read from a primary source; 10/20/40 keV NuSTAR entries rely on a secondary summary of arXiv:2405.17861 Fig.3 which was never numerically read, and the 50 keV SPI entry has a 7-dex lifetime vs mixing mismatch (tool tau 7.8e26 s at 3e-14 vs quoted 1e20 s). Tool support is thin: only 7.1 keV/1e-10 and 20 keV/1e-12 were run through predict_sterile_nu_xray_line, with no contrasting 40-50 keV low-mixing point where INTEGRAL/SPI dominates and BBN Delta N_eff is negligible.

2. Deepen the weakest production-mechanism / structure-formation claim (f-018/f-021/d-09 blocked): settle the DW normalization factor 10-17x dispute, quote the Viel+2005 m_th->m_s coefficient verbatim, and test SF vs DW at a contrasting low-mixing point. — Viability table (f-018) rests on abstracts only for 3/4 2024-2026 papers (2502.17374, 2609.31340, 2601.03346); the DW Omega_s h^2=0.12 line differs by 10-17x between server (2.55e-10 at 7.1 keV) and Abazajian arXiv:1705.01837 Eq.37 (3.0e-9 at 7.1 keV) without verbatim Eq.37 quote; the Viel+2005 m_s=4.43 keV*(m_th/1keV)^{4/3} coefficient

was used but never quoted; SF L>~0.5 viable region (2507.18752: m_s>~10 keV, sin^2 2theta<~1e-14) cannot be tested by server (L cap 0.1, heuristic Delta N_eff=0.1xDW, no xi_e). No contrasting SF vs DW grid at same mass/mixing exists.

3. Synthesize all prior and new results into an updated joint BBN+X-ray report with provenance and robustness checks. — Board has 10 directions with fragmented findings (f-001 to f-022, x-01/x-02) and two blocked/open items (d-09 bibliography, d-06 Viel quote); the final deliverable requires a single reproducible report that integrates the two deepened claims above, corrects the factor-3/10x normalization and SPI mismatch, and provides explicit BBN (Delta N_eff, Yp, D/H) and X-ray (Gamma, tau, E_gamma, flux) numbers per mechanism. Critic's view: revise — SPI lifetime mismatch (tool tau 7.8e26 s vs quoted 1e20 s at 50 keV/3e-14) cannot be resolved without primary SPI paper. web_search step is vague ('e.g. Boyarsky/Roach') - must target specific arXiv ID (e.g. 2008.02283, 2207.04572, or 2405.17861 SPI comparison) and cite verbatim definition of sin^2 2theta normalization, f_DM=1 assumption, and profile/J-factor used for conversion.; get_paper_figures returns images+captions only, not numeric tables. Claiming 'numerically read Fig.3 values at 7,10,20,40 keV' will be manual digitization - must be labeled as approximate with estimated uncertainty and figure number, not as exact tool output, to remain verifiable.; DW normalization 10-17x dispute requires verbatim Abazajian arXiv:1705.01837 Eq.37 quote with URL via cite(). Plan includes this but success depends on capturing full equation including 0.527*erfc term and noting T_QCD 150-200 MeV uncertainty; without quote the corrected table is unverifiable..

Wave 1 — now exploring, in parallel: Deepen the weakest X-ray decay-line claim (f-017/x-02): rebuild the 7.1/10/20/40/50 keV sin^2 2theta limit table from primary sources and rerun the X-ray/BBN emulator at a contrasting high-mass SPI-dominated point.; Deepen the weakest production-mechanism / structure-formation claim (f-018/f-021/d-09 blocked): settle the DW normalization factor 10-17x dispute, quote the Viel+2005 m_th->m_s coefficient verbatim, and test SF vs DW at a contrasting low-mixing point.; Synthesize all prior and new results into an updated joint BBN+X-ray report with provenance and robustness checks..

Finding: Sterile-nu server BBN baselines are Yp=0.2449±0.004 (Aver, Olive & Skillman JCAP 07 2021 029), D/H=2.547±0.025e-5 (Cooke, Pettini & Steidel ApJ 855 2018 102), Planck N_eff=2.99±0.17 (TT,TE,EE+lowE+lensing+BAO), with BBN fit validity N_eff 2.044–6.044, omega_b h2 0.019–0.0257, tau_n 866.4–890.4 s and 95% exclusion Delta chi2>3.84

Finding: Prior run 261021_110150 produced DW scan CSV/NPZ (scan_DW_dc7743), BBN vs N_eff plot (bbn_vs_neff.png), exclusion plane (exclusion_scan_DW_dc7743.png), and 6 sterile-nu grid CSVs (DW and SF mechanisms) plus references.bib with 5 papers

Finding: DW vs SF at m_s=20 keV, sin^2 2theta=1e-14: DW gives Delta N_eff=1.42e-07, Omega_s h^2=3.04e-05, Delta chi2_BBN=-0.0 (BBN-allowed, not overclosing); SF (L=0.1 max, heuristic 0.1xDW) gives Delta N_eff=1.42e-08, Omega_s h^2=4.90, Delta chi2_BBN=-0.0 (BBN-allowed but overcloses by 40x); at 50 keV, 1e-14: DW Omega_s h^2=1.58e-04, SF Omega_s h^2=30.6, both BBN-allowed, SF overcloses by 255x, demonstrating server SF heuristic is unphysical at L=0.1 and cannot test L>0.5 viable region.

Finding: Contrasting X-ray decay-line emulator at m_s=40 keV (E_gamma=20 keV), sin^2 2theta=3e-14 gives Gamma=4.18e-28 s^-1, tau=2.39e27 s (7.58e19 yr), not excluded by tabulated NuSTAR/XMM limits; and at m_s=10 keV (E_gamma=5 keV), sin^2 2theta=1e-12 gives Gamma=1.36e-29 s^-1, tau=7.35e28 s, also not excluded by built-in limits (whole-halo flux, f_DM=1, no FOV cut).

Finding: DW BBN emulator at high-mass SPI regime m_s=40,50 keV with sin^2 2theta=1e-12,3e-14,1e-14 gives Delta N_eff=2.5e-5 to 2.5e-7, Delta chi2_BBN~0, Omega_s h^2=0.0001-

0.016, tau=2.4e25-7.2e27 s; all 6 points BBN-allowed and not overclosing, confirming BBN is negligible at these low mixings and X-ray/SPI dominates.

Completed — Synthesize all prior and new results into an updated joint BBN+X-ray report with provenance and robustness checks.. (no summary)

Finding: Abazajian 1705.01837 Fig.7 extracted: X-ray line detections consistent with 7.1 keV sterile neutrino DM (Bulbul+ MOS/PN stacked clusters, Perseus core-removed, M31, Galactic Center) vs 90% constraints from Chandra M31, stacked dwarfs, Suzaku Perseus; saved to runs/261102_164917/figures_1705.01837/fig07.png with caption.

Finding: Viel et al. astro-ph/0501562 Figs.1-3 extracted: WDM transfer function T(k) for thermal masses 92-1441 eV and mixed LambdaCWDM, flux power spectrum fractional difference for m_WDM=0.5-8 keV at z=2.5-4, and bias function b^2(k) for 1 keV WDM; saved to runs/261102_164917/figures_astro-ph_0501562/fig01_1.png, fig01_2.png, fig02.png, fig03.png.

Finding: Primary NuSTAR 11-yr stray-light paper arXiv:2405.17861 Fig.1 extracted: 95% CL sin^2 2theta upper limits vs m_s from unfocused stray-light spectrum (|b|>3 deg, 117 Ms/FPM), with previous NuSTAR 2020/2023 and XMM 2021 constraints overplotted; borderline excess at 40 keV noted as instrumental absorbed stray-light effect.

Blocked — Deepen the weakest production-mechanism / structure-formation claim (f-018/f-021/d-09 blocked): settle the DW normalization factor 10-17x dispute, quote the Viel+2005 m_th->m_s coefficient verbatim, and test SF vs DW at a contrasting low-mixing point.. (Tool budget exhausted after 4 calls; read_arxiv_chunk/cite for Abazajian Eq.37, Viel coefficient, and Vogel 2507.18752 verbatim quotes could not run. DW normalization 10-17x dispute and m_th translation table remain unquoted/uncomputed. Server SF L<=0.1 cap prevents testing L>0.5 region computationally.) Contrasting DW vs SF grid at m_s=20 keV and 50 keV, sin^2 2theta=1e-14 completed: DW (runs/261102_164917/sterile_nu_grid_DW_44fa6 gives Delta N_eff=1.42e-07 (20 keV) and 2.95e-07 (50 keV), Omega_s h^2=3.04e-05 and 1.58e-04, Yp=0.246815, D/H=2.443e-5, Delta chi2_BBN=-0.0, BBN-allowed, not overclosing; SF L=0.1 heuristic (runs/261102_164917/sterile_nu_grid_SF_d58c80.csv) gives Delta N_eff=1.42e-08 and 2.95e-08 (0.1xDW heuristic), Omega_s h^2=4.90 and 30.6, Delta chi2_BBN=-0.0, BBN-allowed but overcloses by 40x and 255x, proving server SF cannot test L>0.5 viable region (L cap 0.1, heuristic, no xi_e, no BR/T_RH). Additional DW grid at 40/50 keV with 1e-12,3e-14,1e-14 in sterile_nu_grid_DW_5d6c37.csv. Figures extracted: Abazajian 1705.01837 Fig.2 (fig02.png) and Fig.7 (fig07.png, Figure 44) showing 3.5 keV detections vs Chandra/Suzaku constraints; Viel astro-ph/0501562 Fig.1 (fig01_1.png, fig01_2.png, Figures 45-46), Fig.2 (fig02.png, Figure 47), Fig.3 (fig03.png, Figure 48) anchoring WDM transfer function and m_th limits, all saved to runs/261102_164917/figures_*/. Blocked: verbatim Abazajian Eq.37 (m_s~3.40 keV*(sin^2 2theta/1e-8)^-0.615...) and Viel m_s=4.43 keV*(m_th/1keV)^{4/3} quotes not fetched (tool budget exhausted, dead end x-07); m_th table at 7.1/10/20/50 keV for three normalizations (server 2.55e-10 vs Abazajian 3.0e-9 at 7.1 keV, 10-17x dispute) not computed; Vogel 2507.18752 L>0.5, m_s>10 keV, sin^2 2theta<1e-14 viable region quotes not fetched; corrected per-mechanism viability table with provenance not posted.

Blocked — Deepen the weakest X-ray decay-line claim (f-017/x-02): rebuild the 7.1/10/20/40/50 keV sin^2 2theta limit table from primary sources and rerun the X-ray/BBN emulator at a contrasting high-mass SPI-dominated point.. (Tool budget (5 calls) exhausted after describe + 2 xray_line + 1 grid + 1 get_paper_figures; XRISM has no HTML rendering [tc-261102_1-w1-d-13-68] and SPI primary not fetched; Fig.3 not yet requested and no cite() calls completed. Need 3-4 additional tool calls: get_paper_figures figures="3" for NuSTAR Fig.3, read_arxiv_chunk+cite for NuSTAR Fig.3 values and XRISM Gamma~1e-27 s^-1 at 7.1 keV, and SPI primary for lifetime conversion definition.) Established:

(4) Primary NuSTAR paper arXiv:2405.17861 Fig.1 extracted [tc-261102_1-w1-d-13-54] to /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261102_164917/figures_2405.17861/fig01.png with caption 95% CL sin^2 2theta limits from 11-yr stray-light (|b|>3deg 117 Ms/FPM) plus NuSTAR 2020/2023 XMM 2021, 40 keV excess instrumental. Findings posted f-060,f-061,f-064. Remaining open: numerically read Fig.3 at 7,10,20,40 keV, fetch XRISM arXiv:2510.24560 (no HTML, needs read_arxiv_chunk) and SPI primary (Boyarsky 2006/Roach SPI) to resolve 1e20 s vs 7.8e26 s mismatch, cite() with verbatim quotes, and post corrected 5-row table (7.1/10/20/40/50 keV) with Gamma_limit sin^2 limit source figure tool Gamma/tau BBN Delta N_eff/chi2 Omega_s h2.

Critic, wave 1 — continue: 4 findings stand up to the evidence, 4 questioned ('Sterile-nu server BBN baselines are Yp=0.2449±0.004 (Aver, Olive & Skillman JCAP 07 2021 0': Evidence tc-261102_1-w1-d-15-22 is generic server help text listing tool names; it contains no Yp, D/H, N_eff values, no validity ranges (N_eff 2.044-6.044, omega_b h2, tau_n), and no Delta chi2>3.84 threshold to support the claimed baselines.; 'DW vs SF at m_s=20 keV, sin^2 2theta=1e-14: DW gives Delta N_eff=1.42e-07, Omega_s h^2=3.0': Evidence tc-261102_1-w1-d-14-51 and tc-261102_1-w1-d-14-52 show only the 20 keV rows (Delta N_eff 1.416e-07/1.416e-08, Omega 3.04e-05/4.898). The claimed 50 keV points (Omega 1.58e-04/30.6), overclose factors 40x/255x, and derived viability interpretation are not in the excerpts.; 'DW BBN emulator at high-mass SPI regime m_s=40,50 keV with sin^2 2theta=1e-12,3e-14,1e-14 ': Evidence tc-261102_1-w1-d-13-26 shows only the first of 6 rows (40 keV 1e-12 Delta N_eff 2.466e-05 Omega 0.01059) and summary counts 0 excluded/0 overclose. It does not contain the full 6-point ranges for Delta N_eff, Omega_s h2, tau, or individual Delta chi2_BBN values claimed.; 'Primary NuSTAR 11-yr stray-light paper arXiv:2405.17861 Fig.1 extracted: 95% CL sin^2 2the': Evidence tc-261102_1-w1-d-13-54 confirms extraction of 4 figures including fig01.png but the excerpt contains no caption text, no 95% CL, no 117 Ms/FPM, no |b|>3 deg selection, and no 40 keV instrumental excess note to support the detailed limit description.).

Issues: X-ray emulator uses whole-halo f_DM=1 with no FOV/J-factor cut; claimed 'not excluded' cannot be verified against NuSTAR stray-light or SPI diffuse limits without primary-paper definition of sin^2 2theta normalization and profile. SPI lifetime mismatch (tool tau 7.8e26 s vs quoted 1e20 s at 50 keV/3e-14) remains unresolved.; Server SF capped at L=0.1 with heuristic Delta N_eff=0.1xDW and no xi_e/BR/T_RH physics; Omega_s h2 4.9-30.6 at 1e-14 is unphysical and cannot test literature L>0.5 viable region (Vogel 2507.18752 m_s>10 keV sin^2<1e-14). DW normalization 10-17x dispute (server 2.55e-10 vs Abazajian 3.0e-9 at 7.1 keV) lacks verbatim Eq.37 quote.; BBN baseline provenance not cited verbatim; brief vs server values (Yp 0.245 vs 0.2449, D/H 2.53 vs 2.547e-5) and Planck N_eff prior impact on Delta N_eff<0.5-0.6 bound not quantified. Report synthesis depends on CSVs/PNGs in runs/261102_164917 without list_files verification..

Next steps after wave 1 — Two weakest claims are X-ray decay-line limits (whole-halo f_DM=1 without FOV/J-factor correction and unresolved SPI lifetime mismatch) and production-mechanism mapping (10-17x DW normalization dispute and unquoted Viel coefficient with unphysical SF L=0.1 heuristic). Blockers were tool-budget exhaustion, now removed with 14 calls available, so d-13 and d-14 are reopened to complete verbatim NuSTAR Fig.3/XRISM/SPI and Abazajian Eq.37/Viel quotes with contrasting 7.1 keV and 50 keV emulator points and m_th translation table. A single new synthesis direction is added to verify prior artifacts, quantify BBN baseline/prior robustness, and write the updated joint report with provenance and validity appendix, keeping total to 3 directions within budget.

New lines of investigation: Synthesize joint BBN+X-ray report with provenance, validity appendix and robustness checks.

Wave 2 — now exploring, in parallel: Deepen the weakest X-ray decay-line claim (f-017/x-02): rebuild the 7.1/10/20/40/50 keV sin^2 2theta limit table from primary sources and rerun the X-ray/BBN emulator at a contrasting high-mass SPI-dominated point.; Synthesize joint BBN+X-ray report with provenance, validity appendix and robustness checks; Deepen the weakest production-mechanism / structure-formation claim (f-018/f-021/d-09 blocked): settle the DW normalization factor 10-17x dispute, quote the Viel+2005 m_th->m_s coefficient verbatim, and test SF vs DW at a contrasting low-mixing point..

Finding: Sterile-nu server BBN baselines confirmed: Yp=0.2449±0.004 (Aver+2021), D/H=2.547±0.025e-5 (Cooke+2018), Planck N_eff=2.99±0.17, BBN fit validity N_eff 2.044-6.044, omega_b h2 0.019-0.0257, tau_n 866.4-890.4 s, 95% exclusion Delta chi2>3.84, m_s<100 keV, X-ray whole-halo f_DM=1 no FOV cut with 10 tabulated limits

Finding: Contrasting X-ray decay-line emulator: m_s=40 keV sin^2 2theta=3e-14 gives E_gamma=20 keV Gamma=4.18e-28 s^-1 tau=2.39e27 s (7.58e19 yr) not excluded; m_s=10 keV sin^2 2theta=1e-12 gives E_gamma=5 keV Gamma=1.36e-29 s^-1 tau=7.35e28 s (2.33e21 yr) not excluded; both whole-halo f_DM=1 no FOV cut, Gamma formula 1.38e-29*(m_s/1keV)^5*sin^2 2theta matches tool within 3%

Finding: DW BBN grid at high-mass SPI regime m_s=40,50 keV x sin^2 2theta=1e-12,3e-14,1e-14 gives Delta N_eff 2.47e-05 to 2.47e-07, Omega_s h2 0.00011-0.0158, Delta chi2_BBN~0, tau 2.35e25-7.18e27 s; all 6 points BBN-allowed and not overclosing, confirming BBN negligible at low mixing where X-ray/SPI dominates; CSV saved to /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261102_164917/sterile_nu_grid_DW_5d6c37.csv

Finding: DW vs SF at m_s=20 keV sin^2 2theta=1e-14: DW Delta N_eff=1.42e-07 Omega_s h^2=3.04e-05 Delta chi2_BBN=0 BBN-allowed not overclosing; SF L=0.1 heuristic Delta N_eff=1.42e-08 Omega_s h^2=4.90 overcloses 40x; at 50 keV 1e-14 DW Omega_s h^2=1.58e-04 SF Omega_s h^2=30.6 overcloses 255x, proving server SF L cap 0.1 heuristic cannot test L>0.5 viable region

Finding: Artifact verification d-16: prior run 261021_110150 contains scan_DW_dc7743.csv/.npz, bbn_vs_neff.png, exclusion_scan_DW_dc7743.png, 6 sterile_nu_grid CSVs, references.bib, 6 paper PDF/TXT pairs (1702.08430, 1705.01837, 2405.17861, 2507.18752, 2510.24560, astro-ph_0501562); current run 261102_164917 contains 3 grid CSVs (DW_44fa64.csv, DW_5d6c37.csv, SF_d58c80.csv) and 4 figure directories (figures_1705.01837, figures_2405.17861, figures_astro-ph_0501562, figures_astro-ph_0602028); out/ directory empty (0 files).

Finding: DW BBN emulator at 40 and 50 keV with sin^2 2theta 1e-12/3e-14/1e-14 gives Delta N_eff 2.5e-05 to 2.5e-07 Delta chi2_BBN~0 Omega_s h^2 0.0001-0.016 tau 2.4e25-7.2e27 s all BBN-allowed not overclosing confirming BBN negligible at low mixing and X-ray/SPI dominates

Research report:

Sterile neutrino DM: BBN + X-ray joint constraints — updated report

Abstract

This run attempted to deepen the two weakest claims from prior work: the X-ray decay-line limit table and the production-mechanism / structure-formation mapping. Two contrasting X-ray emulator points and a six-point BBN grid at 40–50 keV were computed locally, and literature figures were extracted for NuSTAR stray-light limits, Abazajian review detections, and Viel et al. WDM transfer functions. Tool budget was exhausted after four calls per direction, so no primary-source verbatim quotes, no numerically read NuSTAR Fig.3 or XRISM limits, no SPI primary fetch, no DW-normalization settlement, and no BBN robustness reruns were completed. The joint BBN+X-ray exclusion therefore remains anchored to prior-run scans and server heuristics with explicit caveats.

Background

Literature describes keV sterile neutrino dark matter constrained jointly by BBN and X-ray decay searches. BBN constraints arise from thermalization via active-sterile oscillations increasing N_eff and altering n/p freeze-out, with relaxation possible via large lepton asymmetry or secret interactions. X-ray constraints come from non-observation of decay lines at E = m_s/2 in stacked clusters, M31, Galactic Center/Bulge and diffuse background with NuSTAR, Chandra and XMM-Newton. The 3.55 keV / 7.1 keV candidate has been extensively tested and largely excluded as DM decay. Production mechanism determines the relic density vs mixing relation and maps to the joint exclusion plane with Lyman-alpha free-streaming limits.

Key literature for this task:

- arXiv:1402.4119 — 7.1 keV sterile neutrino decay interpretation of the 3.55 keV line; defines X-ray line flux vs mass/mixing target.
- arXiv:1402.2301 — independent detection claim for the 3.55 keV line; motivates X-ray line search methodology.
- arXiv:1904.05710 — NuSTAR M31 / Galactic bulge X-ray line search with focused+unfocused FOV treatment.
- arXiv:1602.04816 — NuSTAR Galactic Center constraints closing the Dodelson-Widrow window.
- arXiv:1408.3503 — joint CMB/BBN N_eff and mass constraints vs short-baseline anomalies.
- arXiv:1103.4570 — comprehensive BBN+CMB+LSS constraints on sterile thermalization and Delta N_eff.

Results

BBN baseline and validity range The sterile-neutrino server reports BBN baselines as Yp = 0.2449 ± 0.004 (Aver, Olive & Skillman JCAP 07 2021 029), D/H = 2.547 ± 0.025e-5 (Cooke, Pettini & Steidel ApJ 855 2018 102), Planck N_eff = 2.99 ± 0.17 (TT,TE,EE+lowE+lensing+BAO),

with CMB-S4 forecast N_eff = 3.044 ± 0.03. The BBN fit validity range is N_eff 2.044–6.044, omega_b h2 0.019–0.0257, tau_n 866.4–890.4 s, 95% exclusion at Delta chi2 > 3.84 (1 dof), m_s < ~100 keV (relativistic at BBN), PRyMordial-calibrated <0.3%. This provenance was captured verbatim from the server description and has not been independently verified against primary observational papers; the brief's alternative baselines Yp = 0.245 ± 0.003 and D/H = (2.53 ± 0.03)e-5 were not reconciled, and the impact of the Planck N_eff prior on the Delta N_eff < 0.5 vs 0.6 bound was not quantified.

Prior-run artifacts and current-run inventory Prior run 261021_110150 produced a DW scan CSV/NPZ (scan_DW_dc7743.csv/.npz), BBN vs N_eff plot (bbn_vs_neff.png), exclusion plane (exclusion_scan_DW_dc7743.png), six sterile_nu_grid CSVs (DW and SF mechanisms), and references.bib with five papers, plus six paper PDF/TXT pairs (1702.08430, 1705.01837, 2405.17861, 2507.18752, 2510.24560, astro-ph/0501562). Current run 261102_164917 contains three grid CSVs (sterile_nu_grid_DW_44fa64.csv, sterile_nu_grid_DW_5d6c37.csv, sterile_nu_grid_SF_d58c80.csv) and four figure directories (figures_1705.01837, figures_2405.17861, figures_astro-ph_0501562, figures_astro-ph_0602028). The out/ directory is empty (0 files); no updated joint report was written in this wave.

X-ray decay-line emulator at contrasting masses Two contrasting X-ray line predictions were computed with the server's whole-halo, f_DM = 1, no FOV cut model (10 tabulated limits). This model assumption means the "not excluded" verdicts are not directly comparable to NuSTAR unfocused stray-light or SPI diffuse limits without primary-paper J-factor/profile and sin^2 2theta normalization.

- m_s = 40 keV, sin^2 2theta = 3e-14: E_gamma = 20 keV, Gamma = 4.18e-28 s^-1, tau = 2.39e27 s (7.58e19 yr), not excluded by built-in limits. Fluxes: Milky Way center (M = 1e12 Msun, d = 0.0083 Mpc) 1.42 ph/s/cm2; M31 (1.3e12 Msun, 0.78 Mpc) 0.000208 ph/s/cm2; Coma (1.2e15 Msun, 99.0 Mpc) 1.19e-05 ph/s/cm2; Perseus (6.6e14 Msun, 77.7 Mpc) 1.07e-05 ph/s/cm2.
- m_s = 10 keV, sin^2 2theta = 1e-12: E_gamma = 5 keV, Gamma = 1.36e-29 s^-1, tau = 7.35e28 s (2.33e21 yr), not excluded. Fluxes: Milky Way center 0.184 ph/s/cm2; M31 2.71e-05 ph/s/cm2; Coma 1.55e-06 ph/s/cm2; Perseus 1.4e-06 ph/s/cm2.

The analytic decay rate Gamma = 1.38e-29 s^-1 (m_s/1 keV)^5 sin^2 2theta matches the tool within 3% at these points. These two points are the only masses in the intended 5-row table (7.1/10/20/40/50 keV) with tool Gamma/tau in this wave; the 7.1 keV and 20 keV entries from prior waves were not rerun here, and the 50 keV SPI-dominated entry remains without primary-source provenance.

BBN impact at high-mass, low-mixing (SPI-dominated) regime A six-point DW grid at m_s = 40 and 50 keV with sin^2 2theta = 1e-12, 3e-14, 1e-14 was computed. All points are BBN-allowed (Delta chi2_BBN ~ 0, bbn_excluded_95 = 0) and not overclosing (Omega_s h2 < 0.12), confirming BBN is negligible at these low mixings where X-ray/SPI dominates. This result relies on the server's BBN mapping and has not been independently verified with a full Boltzmann code.

CSV: /Users/nramachandra/hep-genesis-testing/projects/ramp-research-sterile-bbn-xray/runs/261102_1649

- 40 keV, 1e-12: Delta N_eff = 2.47e-05 (2.46585e-05), Omega_s h2 = 0.0106 (0.0105898), tau = 7.18e25 s (7.17533e25 s), Yp = 0.246815, D/H = 2.44334e-5, chi2_bbn = 2.7711, Delta chi2 = -0.0003, free-streaming = 26.87 kpc
- 40 keV, 3e-14: Delta N_eff = 7.40e-07 (7.39754e-07), Omega_s h2 = 0.00032 (0.000317695), tau = 2.39e27 s (2.39178e27 s)
- 40 keV, 1e-14: Delta N_eff = 2.47e-07 (2.46585e-07), Omega_s h2 = 0.00011 (0.000105898), tau = 7.18e27 s (7.17533e27 s)
- 50 keV, 1e-12: Delta N_eff = 2.95e-05 (2.94777e-05), Omega_s h2 = 0.0158 (0.0158244), tau = 2.35e25 s (2.35121e25 s), free-streaming = 21.49 kpc
- 50 keV, 3e-14: Delta N_eff = 8.84e-07, Omega_s h2 = 0.00047, tau = 7.84e26 s
- 50 keV, 1e-14: Delta N_eff = 2.95e-07, Omega_s h2 = 0.00016, tau = 2.35e27 s

Production mechanism comparison: Dodelson-Widrow vs Shi-Fuller At m_s = 20 keV, sin^2 2theta = 1e-14: DW gives Delta N_eff = 1.42e-07 (1.416e-07), Omega_s h2 = 3.04e-05 (3.041e-05), Delta chi2_BBN = 0, BBN-allowed and not overclosing. The server's SF model at L = 0.1 (heuristic 0.1×DW, no xi_e, no BR/T_RH physics) gives Delta N_eff = 1.42e-08 (1.416e-08), Omega_s h2 = 4.90 (4.898), BBN-allowed but overclosing by ~40×. At 50 keV, 1e-14: DW Omega_s h2 = 1.58e-04, SF Omega_s h2 = 30.6, overclosing by ~255×. This demonstrates the server SF implementation is unphysical at L = 0.1 and cannot test the literature L > 0.5 viable region (Vogel arXiv:2507.18752: m_s > 10 keV, sin^2 2theta < 1e-14). The DW normalization dispute (server 2.55e-10 vs Abazajian arXiv:1705.01837 Eq.37 3.0e-9 at 7.1 keV, factor 10–17×) remains unresolved; no verbatim Eq.37 quote with 0.527×erfc term and T_QCD 150–200 MeV uncertainty was captured.

Literature figure extraction Four figure sets were extracted to the current run; no numeric digitization or verbatim quoting was performed due to budget exhaustion.

NuSTAR 11-yr stray-light paper arXiv:2405.17861 Fig.1 was extracted, showing 95% CL sin^2 2theta upper limits vs m_s from the unfocused stray-light spectrum (|b| > 3 deg, 117 Ms/FPM) with previous NuSTAR 2020/2023 and XMM 2021 constraints overplotted; the borderline excess at 40 keV is noted as an instrumental absorbed stray-light effect. This extraction has not been independently verified against a primary-source numeric table, and Fig.3 (observed vs expected limits at 7,10,20,40 keV) was not numerically read.

[[FIGURE 39]] Figure 39 shows NuSTAR 95% upper limits on sin^2 2theta from the unfocused stray-light spectrum with previous constraints overplotted.

[[FIGURE 40]] Figure 40 shows the NuSTAR FPMA+FPMB combined spectrum of the unfocused stray-light sky background at |b| > 3 deg.

[[FIGURE 41]] Figure 41 shows the sky distribution of 3248 (FPMA) and 3139 (FPMB) NuSTAR observations in Galactic coordinates.

[[FIGURE 42]] Figure 42 shows NuSTAR detector count rate vs time with a cubic polynomial outlier-resistant approximation and exclusion threshold.

Abazajian arXiv:1705.01837 Fig.7 was extracted, showing X-ray line detections consistent with 7.1 keV sterile neutrino DM (Bulbul et al. MOS/PN stacked clusters, Perseus core-removed, M31, Galactic Center) vs 90% constraints from Chandra M31, stacked dwarfs, Suzaku Perseus. Fig.2 (lepton asymmetry sign vs mass splitting and mixing) was also extracted.

[[FIGURE 43]] Figure 43 shows the final sign of the lepton asymmetry vs mass splitting and mixing angle for nu_tau <-> nu_s mixing.

[[FIGURE 44]] Figure 44 shows X-ray line detections consistent with sterile neutrino DM with 1,2,3 sigma regions from stacked clusters, Perseus, M31 and Galactic Center.

Viel et al. astro-ph/0501562 Figs.1–3 were extracted, showing WDM transfer function T(k) for thermal masses 92–1441 eV and mixed LambdaCWDM, flux power spectrum fractional difference for m_WDM = 0.5–8 keV at z = 2.5–4, and bias function b^2(k) for 1 keV WDM. The Viel coefficient m_s = 4.43 keV (m_th/1 keV)^{4/3} was not quoted verbatim, no m_th translation table at 7.1/10/20/50 keV was computed, and the half-mode vs free-streaming definition shift remains open.

[[FIGURE 45]] Figure 45 shows the WDM transfer function T(k) for pure LambdaWDM models with T_x/T_nu = 0.5–0.2 corresponding to m_x = 92–1441 eV, with analytic fits.

[[FIGURE 47]] Figure 47 shows fractional difference of flux power spectrum for LambdaWDM vs LambdaCDM for thermal WDM masses 0.5–8 keV at z = 4, 3, 2.5.

[[FIGURE 48]] Figure 48 shows bias function b^2(k) between flux power spectrum and linear matter power spectrum for LambdaCDM vs LambdaWDM with
